
PRONOUNCED POLYPLOIDY IN ROOT TIP OF RYE, GROWN IN A MIXED SOLUTION OF 1·75 P.P.M. DIBENZANTHRACENE AND 0·25 P.P.M. ETHYL MERCURIC CHLORIDE. SEPARATE SOLUTIONS AT THESE CONCENTRATIONS GAVE ONLY DIPLOID NUCLEI ($2n = 14$). (× 750.)

Stock solutions of ethyl mercuric chloride and dibenzanthracene were made by dissolving 1 mgm. of each chemical in alcohol and diluting to the required proportions with tap water. Both substances were difficult to dissolve in water alone and this procedure was necessary to obtain exact dilutions. The final mixtures contained 0·4 per cent alcohol. The dibenzanthracene which is soluble in water only to the extent of 0·001 part per million[4] was a colloidal suspension and therefore saturated; the ethyl mercuric chloride was a clear solution. In a supplementary experiment, as reported by Levan and Ostergren[2] for colchicine, we found that this trace of alcohol showed a slight antagonism and lifted the lower threshold value of action. The accompanying table summarizes our results on the action of these compounds on the root tips of rye seedlings, after 48 hr. treatment at 22° C.

Parts per million of water		Effects*		
Dibenz-anthracene	Ethyl mercury chloride	*c*-Mitosis	Toxicity	Polyploidy
1	*0*	—	—	—
0	*1*	+	++	—
1	*1*	—	++	—
1·5	*0·5*	+	++	—
0	*0·5*	+	+	+
1·75	*0*	—	—	—
0	*0·25*	—	—	—
1·75	*0·25*	+++	—	++

* The *c*-mitosis column shows the degree of spindle disturbance—the toxicity is measured in inverse proportion to the number of accumulated active nuclei after 48 hours.

It will be noticed that only very minute concentrations of the reagents are involved and that there is a limited range of effectiveness. Dibenzanthracene alone has no effect on mitosis at any concentration while ethyl mercuric chloride alone has a slight effect at 0·5 part per million. Ethyl mercuric chloride alone has no effect at 0·25 part per million, but in conjunction with dibenzanthracene the polyploidogenic effect is pronounced (see accompanying illustration).

Evidently the ethyl mercuric chloride is the direct polyploidogenic agent and the dibenzanthracene facilitates its action. The observation by Lisle[5], which we have confirmed, that dibenzanthracene reduces the ability of lipoids to inhibit the oxidation of fats may show how this comes about.

It is too early to decide the exact role of these two reagents, and systematic study of pairs of simila substances is needed, but this example of a complementary action suggests a new line of attack in both chromosome and cancer research.

Relapsing Fever and *B. proteus X Kingsbury*

WHILE in Ethiopia with a mobile bacteriological laboratory, it was noted that there was an association between the findings of blood spirochætes and an agglutination of *B. proteus X Kingsbury*. Of 650 cases in which Borrelia were found and which were tested for agglutinations, 211 gave agglutination of *Kingsbury* in dilutions of 1/100 and more. An examination of specimens submitted for Kahn test failed to reveal a corresponding high level in 'normal' individuals, and the testing of malaria cases disposed of the possibility of an 'anamnestic' type of reaction.

A series of 110 cases in which spirochætes were found was followed up with agglutination reactions every fourth day. These cases were for the most part under arsenical treatment. Some had relapses and some died. Their responses to *B. proteus X Kingsbury* were as follows:

Clinical course	Agglutination of *Kingsbury* in 1/100	
	Positive	Negative
No relapse	6	35
One or more relapses	22	27
Deaths	—	20

In those relapsing cases which responded there was a progressive rise of titre, in one case reaching 1/6400. Immediately after what was to prove the last relapse there was a rapid fall in titre; and a month after it had completely disappeared, that is, less than 1/50.

We had cases showing agglutinations in which spirochætes were never demonstrated. Some of these were treated empirically as relapsing fever, and recovered, but some others gave a 'typhus' picture.

These cases were all in the highlands where Ornithoiorus is unknown, and judging by the parallelism with epidemic typhus were probably louse-borne.

Unfortunately, the exigencies of the Service did not permit of further investigation.

Glycogen in Adipose Tissue after Insulin Injection

WHEN insulin is injected into a normal rat of about 100 gm. maintained on an ordinary diet, a transient appearance of glycogen is demonstrable in the adipose tissue. If, after the glycogen has disappeared, the insulin injection is repeated, new transient deposition of adipose glycogen is induced. It should be added that different types of adipose tissue differ quantitatively from one another in ability to store glycogen following insulin treatment. In general, deposition occurs most rapidly in the brown interscapulary adipose, less rapidly in mesenterial adipose, and least rapidly in other adipose stores. Seasonal fluctuations, too, are of importance. In summer, the demonstration of deposition necessitates no particular precautions; in winter, deposition occurs less rapidly and then only if the animals are maintained above 21° C. on a diet of high calorific value, and if relatively large doses of insulin are administered. Protamin-zinc-insulin is of greater effectivity than ordinary insulin. The adipose tissue of rabbits is less active[1]. The effect of insulin in this animal is smaller and only detectable after sugar feeding.

Representative experiments which illustrate the above effects are given in Table 1.

TABLE 1.

Month	Prot.-Zn.-Insulin	Duration of exp. (hr.)	Glycogen gm./100 gm. adipose tissue			Blood sugar	No. of expts.
			Intersc. fat	Mesent. fat	Total fat		
March/April	2×1 unit	7	0·30	0·15	0·052	74	10
Feb.	2×3 units	7	0·29	0·12	0·045	62	19
	Controls	7	0·03	0	0	118	15

July. Administration of 1 × 1 unit prot.-Zn.-insulin

Glycogen gm./100 gm. in adipose tissue after	1½	3	4	5	6	7	9–10
	hours						
Interscap. fat ..	0·19	0·14	0·16	0·21	0·28	0·40	0·08
Mesent. fat ..			0·05	0·12	0·14	0·15	0·04
Total fat				0·04	0·04	0·07	0

Each value quoted represents the average of at least four experiments. Controls in seven random tests showed no glycogen in adipose tissue.

Glycogen deposition always occurs in adipose tissue when fat synthesis from carbohydrates is taking place, for example, following intake of a carbohydrate-rich meal after a period of fasting[1], following carbohydrate abundance without previous fasting or when animals are subjected to alternate periods of hunger and feeding as in the experiments of MacKay and Drury[2]. The occurrence of stable fat deposition in man following prolonged insulin treatment has long been known[3]. MacKay and collaborators[4] have carried out a precise study of this effect in rats. It seems justifiable, therefore, to assume that the glycogen deposition in adipose tissue following injection of insulin is merely a preliminary of fat deposition.

The observation has repeatedly been stressed that the insulin effect is associated with stimulation of appetite for carbohydrates and consequent increase in the carbohydrate intake. It was of importance accordingly to ascertain whether the deposition of glycogen in adipose tissue following insulin administration is secondarily induced and a result of increased carbohydrate intake, or a primary effect of the direct action of insulin on the adipose. The following experiments seem to support the latter explanation alternative: (1) In summer experiments, glycogen deposition in interscapulary adipose is already demonstrable within one hour of insulin injection. (2) Glycogen deposition in adipose tissue occurs rapidly following insulin injection also in rats maintained on a protein-high diet (70 per cent casein, 20 per cent carbohydrates, 10 per cent fat), although appetite and food intake in these animals, as is well known, are not stimulated by insulin[5]. Moreover, glycogen deposition in interscapulary adipose is induced in such rats, even if they are fasted on the day prior to, as well as during, the experiment period (see Table 2). (3) Adrenalectomized rats do not respond to insulin with increased appetite, but nevertheless show clear-cut deposition of glycogen in their adipose tissue following insulin injection. The same experiments and others with adrenalin show, furthermore, that glycogen deposition in the adipose tissue cannot be due to increase in blood adrenalin as a result of insulin administration.

TABLE 2.

	No. of expts.	Glycogen gm./100 gm. adipose tissue			Blood sugar
		Total fat	Mesent. fat	Inter-scap. fat	
Diet: 70% casein; after 20 hr. fasting $2 \times 0{\cdot}3$ U.Pr.Z.Ins.; 5 hr. later sacrificed	5	0	0	0·30	47
Adrenalect. rats; drink: 25% glucose in Rubin-Krick sol. during 30 hr.; in the evening and in the morning —1 U.Pr.Z.Ins.; sacrificed 6 hr. after morning injection	10	0·26	0·46	0·16	63
Controls without insulin	7	0	0	0·03	104

It follows that the effect of insulin is direct on the adipose tissue; and almost certainly that glycogen deposition in the adipose tissue is a preliminary of a larger process which the adipose tissue realizes. A new proof is thus obtained for the view that adipose tissue plays an active part in carbohydrate-fat metabolism.

The bearing of these findings on the theory of insulin action remains to be considered.

(1) The insulin influence on adipose tissue constitutes clear evidence that insulin is concerned in glycogen synthesis. In absence of insulin, adipose tissue normally is void of glycogen.

(2) With reference to the question whether storage of glycogen in adipose tissue has significant bearing on the carbohydrate balance during the period of reaction to insulin, it may be pointed out that the amounts of glycogen actually found in the adipose are in themselves insufficient to be of great significance in relation to the total carbohydrate balance. It should be borne in mind, however, that the found adipose glycogen is in fact a resultant of concurrent processes of synthesis and decomposition. It is certain only that glycogen is being transformed. The finding of glycogen is thus in itself merely evidence of the existence of the adipose-insulin relation. Earlier investigations and the fact that insulin administration leads to fat deposition support the assumption that glycogen is converted in adipose tissue into fat. We believe, therefore, that the primary effect of insulin on adipose tissue is to induce glycogen deposition, and assume that deposed glycogen is then automatically converted by the tissue into fat. Thus we arrive at a factor in insulin action similar to that convincingly educed on quite different grounds by Pauls and Drury[6]: a transient storage of ingested carbohydrate as fat. Insulin may be regarded as an accelerant of this process by virtue of its effect on adipose synthesis of glycogen.

Details of this investigation will be published elsewhere.

Newt Larvæ in Brackish Water

MR. ERIC HARDY, in referring[1] to Miss Helen Spurway's observation of newt larvæ in brackish water[2], states that "the brackish 'slacks' or pools between the west Lancashire coastal dunes from Ainsdale to Formby have long been inhabited by breeding specimens of the common smooth newt, common frog, common toad and natterjack toad". C. T. Green, in his Flora[3], states that "both salt and freshwater plants live in separate, though adjoining areas. The salt and the fresh water here have been readily distinguished by taking their specific gravity".

It occurred to us to test the accuracy of the term 'brackish' as applied to-day to the permanent water on the Freshfield to Ainsdale dunes, and samples were taken this summer from long-standing and well-known slacks and pools and analysed for chloride content, with the following results:

June 1943	Bullrush slack	10·9 parts of sodium chloride per 100,000.
	Drainage pool on an inland slack	8·4 parts of sodium chloride per 100,000.
July 1943	Bullrush slack	10·7 parts of sodium chloride per 100,000.
August 1943	Drainage pool on an inland slack	8·0 parts of sodium chloride per 100,000.

The water samples showed 27–29 parts of calcium carbonate per 100,000 with 21·5–24·5 parts of calcium carbonate per 100,000 as temporary hardness. Hardness due to magnesium salts was very slight. The *p*H values varied from 7·6 to 8·0.

It would thus appear that much, if not most, of the water on the West Lancashire dunes is not 'brackish' at the present time, though doubtless there have been times when localities between Ainsdale and Hightown have had a more brackish character; but records of past years should not be applied indiscriminately to the present.

It may be of interest to note that one of us (F. B.) observed on May 2, 1943, in the saline waters near Nantwich Salt Spring, amphibian larvæ of large size, living in a salinity of 312·3 parts of sodium chloride per 100,000.

Slip and Twinning in Single Crystals of Mercury

IN 1935 Prof. E. N. da C. Andrade and Mr. P. J. Hutchings described[1] the results of interesting experiments on the deformation of single crystals of mercury, and it is concluded that in a mercury crystal the rhombohedral faces are the glide planes—as (it was stated) would be expected from the fact that these are the planes of closest packing. Of many measurements that had been made of the intersection angles between glide and twinning plane traces, three sets in particular were considered to furnish strong confirmation of the above conclusion.

I have recently had occasion to examine this analysis, and, as a result, would make the following observations:

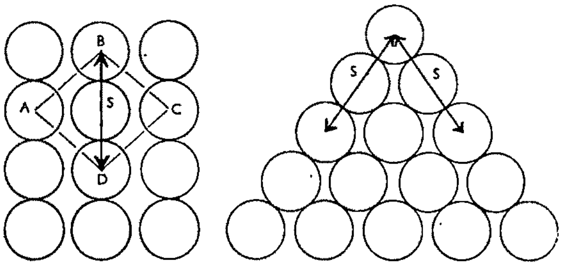
Not the rhombohedral faces {100} but the pyramidal planes $\{11\bar{1}\}$ are those most closely packed in the mercury crystal lattice. This is readily seen on laying out the atomic positions, as in the accompanying diagram, in which the {100} packing is shown at (*a*) and the $\{11\bar{1}\}$ packing at (*b*). It will be seen that while the {100} planes contain one line of close packing—the short diagonal of a rhomb face—the three $\{11\bar{1}\}$ planes each contain the two short diagonals of adjacent rhomb faces, and therefore must be more closely packed than the {100} planes.

This fact necessitates a reconsideration of the main conclusion of Andrade and Hutchings' analysis—that the rhomb faces are the glide planes. The position is, that if the {100} planes are the glide planes, as appeared to be indicated by the recorded angular measurements, which fulfil the geometrical requirements, then glide in mercury crystals does not follow the general rule for face-centred metals, namely, that it takes place on the most densely packed plane.

On the other hand, if glide actually does take place on the most densely packed plane (shown above to be $\{11\bar{1}\}$), then the measurements recorded as satisfying {100} glide must correspond also with the geometrical requirements for the $\{11\bar{1}\}$ mode of glide, which will be a curious coincidence.

Calculation shows that this coincidence actually exists, thus: (1) Double glide was observed on surfaces symmetrically disposed in relation to an axis of the mercury wire examined. The angle between the two planes was 74·4° which, corrected for elongation, gave 78·8° as the original dihedral angle. It was pointed out that the smaller dihedral angle between rhomb faces is 80·3°, and this close correspondence was adduced as evidence for glide on rhomb faces. Calculation shows, however, that the dihedral angle between two $\{11\bar{1}\}$ planes is 75·5°, so that this particular observation may well be considered as evidence for glide on $\{11\bar{1}\}$ planes. Andrade and Hutchings reported having measured several cases of double glide, in every case finding the corrected included angle to be slightly less than 80·3°.

(2) Several measurements were taken of the angle between the slip lines and the twinning plane {110}. The measured angles varied between 75° and 77·5°. The calculated angle being 77·4°, the correspondence was held as additional confirmation of {100} glide. However, calculation shows that the angle between the {110} (twinning plane) and either of two $\{11\bar{1}\}$ pyramidal planes is 82·3°, which appears to be sufficiently near the observed angles to be considered as evidence for $\{11\bar{1}\}$ glide. The crystal in which the value of 75° was obtained was stated by Andrade and Hutchings to be not very favourable for measurement.



{100} packing {11$\bar{1}$} packing

COMPARISON OF ATOMIC PACKING ON DIFFERENT PLANES OF SINGLE MERCURY CRYSTAL.

(3) The third set of measurements were those made on a wire extended to rupture. Traces of glide on the surface of rupture were observed to make an angle of almost 50° with a line of commencing rupture parallel to the long diagonal of a rhomb face, and this is stated to agree with the value of 49·1° to be expected if the glide direction is a short diagonal of the rhomb face. Calculation shows that traces of {100} planes on the adjacent rhomb faces make an angle of 40·9°, with lines parallel to the long diagonal. This is 9° different from the observed angle. If the line of commencing rupture seen was unmistakably parallel to the long diagonal, traces of a $\{11\bar{1}\}$ plane on a twinning plane {110} could make with that line an angle of 52·9°, which may be considered sufficiently near 50° (observed) to be held as confirmation of $\{11\bar{1}\}$ glide. This then requires (*a*) the observed surface of fracture to be a twinning plane in order to explain the existence of the long diagonal as a commencing line of rupture, and (*b*), the final fracture by direct separation. It is suggested this is a probable mode of fracture at the part of the crystal concerned.

With regard to the glide direction, the evidence remains in favour of this being the short diagonal of the rhomb face, while in regard to the twinning plane, no contradiction is involved in accepting the evidence for {110}.

Summing up, it would appear that: (*a*) the $\{11\bar{1}\}$ planes are those most closely packed; (*b*) glide takes place on these planes; (*c*) the direction of glide is the short diagonal of the rhomb face; (*d*) there are two such glide directions in each glide plane.

Magnesium Elektron, Ltd.,
Clifton Junction,
Manchester.

---

[1] Andrade, E. N. da C., and Hutchings, P. J., *Proc. Roy. Soc.*, A, 148, 120 (1935).

MR. FISHER is, I expect, right when he points out that the $\{11\bar{1}\}$ planes are the most closely packed in a mercury single crystal, although I have not the time to check the work. The experiments to which he refers were carried out some years ago, and all notes referring to them were destroyed with my laboratory. Whether he is right in his surmise that the $\{11\bar{1}\}$ planes may be the glide planes I cannot say. The only way of settling the question satisfactorily is by the X-ray method. I always intended to get the attribution checked in this way, but at the time when the work was done an X-ray set suitable for this purpose had not been installed, as it was later. We were discussing the X-ray determination in my laboratory shortly before the War broke out.

It is not, of course, necessary that the most closely packed planes should be the glide planes in all cases, although the most closely packed direction is always the glide direction. This emerges very clearly from some work which I carried out with Dr. Y. S. Chow[1] on body-centred cubic crystals. The matter of the glide plane must, therefore, remain open until I, or someone else, put it to the X-ray test.

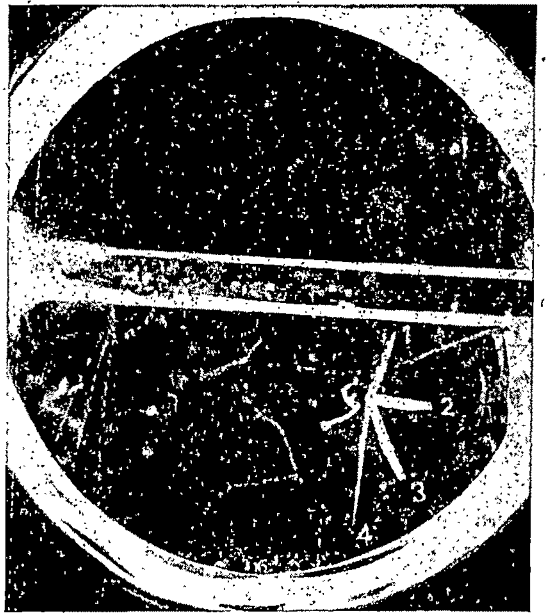
Photograph of a Nuclear Disintegration in a Wilson Chamber

THE presence of heavy ionization tracks has often been observed in Wilson chamber photographs; those due to the emission of α-particles from radioactive impurities can be easily eliminated. The rest are due to nuclear disintegrations produced by cosmic rays. Usually they emerge from lead plates placed inside such chambers. Photographs of disintegrations originating in the gaseous volume of a Wilson chamber are rare; so far as is known to us, Anderson and Neddermeyer[1] have photographed one, and Zlotowsky[2] another. The particles are supposed to be produced by a nuclear evaporation process leading to the emission of both protons and neutrons; in some cases α-particles have also been detected amongst them.

The accompanying photograph shows the emission of four ionizing particles from a nucleus in the gaseous volume of a Wilson chamber filled with oxygen. From the density of ionization along their tracks, the particles appear to be heavier than α-particles and are multiple-charged. As in Anderson's photograph[1], the emitted particles are confined within a hemisphere, and conservation of momentum requires that either a number of neutrons have been emitted in the opposite direction or that a fast non-ionizing particle is responsible for the disintegration—the latter assumption appears more reasonable. A faint mesotron track is seen to cross the lead plate (2·2 cm. thick) and follow the continuation of track 4; it cannot be taken to be responsible for the process of disintegration, as the track in question does not show any scattering or change in ionization density after passing the point of origin of the disintegrated nucleus. Tracks 1 and 4 are of a similar nature; both show jagged outlines, due to ionization by recoil ions produced by nuclear collisions with the primary charged particles; the ionization density along the track of the particle diminishes. Such ionization tracks are to be expected of slow multiple-charged heavy particles, the effective charge of which diminishes with velocity, due to successive neutralizations. Such tracks have been observed in Wilson chamber photographs of fission of the uranium nucleus[3].



THE RANGES OF TRACKS 1, 2, 3 AND 4 CONVERTED TO NORMAL PRESSURES ARE 5·33, 4·76, 6·56 AND 9·01 CM. RESPECTIVELY.

Tracks 2 and 3 are broad and of uniform width throughout their whole lengths, except near the very end where there is a sharp fall of ionization—due to partial neutralization of charges on the ionizing particles. These tracks are similar to those due to α-particles except they are broader; they may be due to doubly-charged heavy particles. The end portions of their tracks are crossed transversely by thin ionization tracks. An obvious explanation of the observed effect is that, due to pure chance, the heavy-particle tracks are crossed at corresponding end points by two electron tracks. But the simultaneous occurrence of such events must be extremely rare. An alternative explanation, which appears to us plausible, is that each of the particles producing the tracks 2 and 3 emits, after it has slowed down, a pair of ionizing particles. In the original photograph, the track crossing the end portion of 3 is slightly bent towards the latter, showing that the particles emitted had a velocity component in the direction of motion of the parent particle. If this explanation is accepted, we have further to account for the fact that the pair of particles are emitted in diametrically opposite directions. This can be accounted for on the assumption that the original nucleus disintegrates into two simpler nuclei which move in opposite directions. Among the lighter nuclei, it is known that ^{8}B produced by the interaction ^{7}Li+^{1}H disintegrates with the emission of a pair of α-particles, the Wilson chamber photographs of which have been obtained by Dee and Walton[4]. The tracks of the pair emitted from the ends of tracks 2 and 3 appear to be too thin to be due to α-particles.

The other alternative is that a pair of (oppositely charged) electrons were emitted from the nuclei of the primary particles. I am not aware that emission of a pair of electrons from an excited nucleus in diametrically opposite directions has been previously observed, and there may be some theoretical difficulty in accounting for such an occurrence.

The interpretation of the origin of the tracks in the photograph given in this communication has arisen out of a discussion with Prof. D. M. Bose, to whom my thanks are due.

Cacao Tannin

THE method most commonly used for the estimation of cacao tannin is by precipitation with cinchonine sulphate[1,2,3]. Duthie[4] found that the filtrate from the cinchonine tannate gave a precipitate on refluxing with formaldehyde and hydrochloric acid (Stiasny reagent). He suggested that this precipitate is a measure of catechin and similar phenolic compounds.

During some experiments in which freshly picked cacao beans were minced and allowed to autolyse, it was found that the amount of tannin, extracted with 40 per cent acetone and precipitated by cinchonine sulphate, decreased progressively with time and that the Stiasny precipitate of the filtrate (residual Stiasny precipitate) decreased proportionally. A Stiasny determination (total Stiasny precipitate) on an aliquot of the original tannin solution yielded a precipitate which was approximately equal to the sum of the cinchonine tannin and the residual Stiasny precipitate (cf. Duthie[4]). These results suggest that the cinchonine sulphate acts selectively on the tannin molecule and combines with a part of it, or that two substances are present, one yielding a precipitate with cinchonine sulphate and the other a Stiasny precipitate, and both substances decrease proportionally with time. The latter explanation seems less likely.

Tannin determinations were also made by a Lowenthal procedure[5]. The amount of tannin estimated by this method (that is, reducing substances fixed by gelatine) was found to run parallel to the residual Stiasny determinations, while the amount of the total substances oxidizable by potassium permanganate closely followed the changes in the amount of total Stiasny precipitate, and the amount of reducing substances not fixed by gelatine followed the changes in amount of tannin precipitated by cinchonine sulphate. It thus appears that in the case of cacao, the cinchonine sulphate reacts with one part of the tannin molecule while gelatine reacts with the other part.

Evidence in support of the above explanation was obtained by making Stiasny determinations on the filtrate from solutions of cacao tannin treated with gelatine and sodium chloride. The values obtained corresponded to the amount of tannin precipitated by cinchonine sulphate from the original solutions.

In this connexion it may be recalled that Smith[6], working with tea infusions, found that the filtrate from the cinchonine tannate gave a colour and precipitate on addition of ferric salts but he was unable to identify the substance responsible. Chapman[7] reported that in the case of hops, the cinchonine tannate filtrate gave a colour with ferric chloride.

Hitherto the results obtained from the two methods of determining tannins have shown little agreement and the above observations offer an explanation and appear to throw fresh light on the structure of the cacao tannin molecule. The cinchonine sulphate and Lowenthal methods may be brought into agreement, so far as cacao is concerned, by taking into account the total Stiasny precipitate, the residual Stiasny precipitate and the cinchonine sulphate precipitate in the one method, and the total reducing substances, reducing substances fixed by gelatine and the reducing substances not fixed by gelatine, in the other method. Certain non-tannin materials which are oxidized by permanganate are present in the cacao bean, but these are very small in amount compared with the amount of tannin. These methods may be applicable to tannin determinations in other plant material if the amount of non-tannin reducing material is known.

A Transverse Zoo-geographical Barrier on the East Side of Lake Tanganyika

No outstanding discontinuity of animal distribution as one proceeds from north to south down the east side of Lake Tanganyika would be inferred from most maps of the region. It is obvious only that along much of the Lake shores the land rises to above 5,000 ft., which has been generally accepted as the approximate lower level of the Highland life-zone in Central Africa. The latest maps[1], which are a great advance on their predecessors, show plainly that on the east side of the Lake the highland country falls into three parts: (*a*) the narrow strip north of Kigoma, which, through Urundi, is continuous with the Kivu and Mufumbiro mountain area, and on the south is separated by the depression centring round the Malagarasi River from (*b*) the much-dissected Kungwe, Mahari, Baholoholo high country, separated on the south by the low gap round Karema from (*c*) the Ufipa Plateau, which is continuous with the highlands on the Northern Rhodesian border and round the head of Lake Nyasa.

A study of the 1/1 mill. map[1] shows that in width the Malagarasi Depression and the Karema Gap are similar, the distance in both between any considerable areas over 5,000 ft. being about eighty miles, but the Karema gap has the flatter bottom, with more of it below 4,000 ft. Looking from the shore of Lake Tanganyika, one gains a strong impression of the Karema gap as a corridor running eastwards, towards the northern end of the Rukwa trough, while the Malagarasi depression is conspicuously hilly.

No vegetation maps of the region in any greater detail than that of Engler[2] exist, and that errs in giving the *Hochweide* too great and continuous a range, right across the Karema gap; but for the present purpose the important point is that evergreen forest remains practically only in small patches in the three highland areas. 'Miombo' (Brachystegia—Isoberlinia) deciduous woodland or, in Ufipa, open grassland, predominates all down the east side of Lake Tanganyika.

From the foregoing it might be expected that the mountain and forest fauna of the Kungwe highland would show northern and southern affinities in roughly equal proportions, with a slight preponderance of the former due to the better 'stepping stones' available across the Malagarasi depression than across the Karema gap. Recent collections of birds made on Kungwe and in Ufipa for the British Museum show that the avifaunal composition on Kungwe differs greatly from expectation, as follows[3]: (1) Total number of species: Kungwe 41, Ufipa 29. (2) Number of 'widespread' species, that is, occurring both farther north and farther south than Lake Tanganyika: Kungwe 16 (39 per cent), Ufipa 17 (58 per cent). (3) Number of purely 'northern' species: Kungwe 21 (51 per cent), Ufipa 3 (10 per cent). (4) Number of purely 'southern' species: Kungwe 2 (5 per cent), Ufipa 9 (31 per cent).

The remaining two species on Kungwe are regarded as endemics; the two 'southern' species on Kungwe are both very strongly marked sub-species, while of the three 'northern' species that reach Ufipa two are subspecifically distinct.

In conjunction with the foregoing evidence we have the fact that the chimpanzee extends south so far as the south edge of the Kungwe highland (latitude 6° 30′ S.), but there is no indication of the animal in Ufipa. The conclusion is that the Karema gap is of much greater zoo-geographical significance than the Malagarasi depression. I am indebted to Mr. Clement Gillman for a discussion of the local geology and for references. Certain of these[4,5,6,7] show an increasing tendency to regard the Karema gap as representing an ancient south-east – north-west rift, which reappears west of Lake Tanganyika in the Lukuga depression at Albertville. This rift was probably earlier than the Rukwa – Nyasa trough and certainly much earlier than the Pleistocene rift now occupied by Lake Tanganyika. Moreover, the efficiency of the Karema gap as a barrier to animals would have been increased by the water connexion that it appears to have provided between Lakes Tanganyika and Rukwa in geologically recent times[8].

In this instance faunistic and admittedly as yet tentative geological evidence give each other powerful support.

Relation between Dissonance and Context

THE effect of musical context on dissonance, di cussed by Gardner and Pickford in NATURE (September 25, is so much a part of the musician everyday experience that he will probably regar an experimental programme to establish the existenc of this effect as entirely redundant.

A simple illustration of the bearing of context o dissonance may be obtained on a pianoforte by pla ing middle *C* together with its seventh (*B* natura and octave. As an isolated sound this is unpleasan Now play the scale of *C* major introducing the ke note and octave each time. This time the effect c the penultimate dissonance is entirely differen although it is precisely the same combination a before. It now takes its place in a regular progression towards the keynote, and when the sevent is introduced the anticipation of the approachin resolution into the major chord is intensely stimulating.

Herein lies the secret of the effect. If the dissonanc is introduced in such a way that the trained ear ca anticipate its resolution by regular progression, the that anticipation gives rise to pleasure which s heavily outweighs the jarring of the isolated soun that this jarring escapes notice and the net effect i one of satisfaction.

I recently ventured to criticize a discord in a com position which one of my friends had just com pleted, and was met by the argument that "Chopi used that discord a great deal". So he did—bu always in a way which gave rise to the pleasurabl anticipation of its resolution.

C. G. GRAY.

IN his interesting letter Mr. Gray has put forwar the theory that dissonances, which he assumes to b constant in harshness whatever their contexts, ma be masked or softened by the pleasure of the music experience of their anticipated resolution, whe heard by a man whose training enables him to mak that anticipation.

Gardner and Pickford, in their letter in NATUR of September 25, explained that the question c pleasure, or rather of liking and disliking, was avoide so far as possible in their experiment. They wer concerned with the more subtle, though no les interesting question, whether the dissonance level o a chord might itself be subject to variation owin to the context, and apart from special musical training. In other words, they raised the question whethe dissonance itself, which is an experience, not a object, may be relative, not the question whethe pleasure may mask it.

The resort to experimental research certainly doe not in any way supersede or render useless exper observations of the kind Mr. Gray is able to mak but it allows us to focus attention upon special point effectively and gives us the opportunity of utilizin carefully balanced evidence. It would be valuabl if Mr. Gray could construct a series of examples o varying complexity which illustrate his theme an which could be used in a short experiment.

VALUE OF HORSE CHESTNUTS AS FOOD FOR PIGS

By R. BRAUDE

National Institute for Research in Dairying, University of Reading

IN time of war the utilization of wild seeds as animal feeding stuffs attracts much attention. Primary consideration is usually given to acorns[1] and horse chestnuts[2], owing to their size and to the quantity in which they could be made available, should their value justify an organized collection.

The chemical composition of horse chestnuts and the figures for digestibility of their components[3] suggest that they should prove a valuable carbohydrate food for livestock. On the other hand, the rather high content of tannic acid (more than 0·25 per cent) which gives them a bitter taste, and the presence of injurious substances like the nitrogen-free glucosides, saponin and esculin, would appear seriously to limit their value as a feeding-stuff.

The evidence available in the literature indicates that the value of horse chestnuts as food for live stock is in fact limited[2], but many of the data are not definite, and sometimes contradictory.

An experiment designed to gain additional information on the value of horse chestnuts as a feeding stuff for pigs seemed worth while, and the following is a brief report on the work carried out in the autumn and winter of 1942–43.

The horse chestnuts used were collected in the neighbourhood of the Institute by local schoolchildren. When given raw the horse chestnuts were not eaten by the pigs, either in their original state or after being crushed. When given to the pigs mixed with meal they were consistently refused, while the meal was completely eaten. Not even by cutting down considerably the meal allowance was it possible to persuade the pigs to eat the chestnuts. Whether this was due to the bitter taste of the nut, or to the reluctance of the animal to take toxic substances, has not been investigated. An experiment was planned to find out whether by preparation the horse chestnuts could be made more palatable to the pigs, and if so, whether their feeding value justifies the trouble and expense connected with the preparation.

Horse chestnuts prepared in three different ways were used: (*a*) dried and ground to a meal, (*b*) boiled, and (*c*) soaked in cold water.

The drying of the horse chestnuts was carried out in a hot-air drier, through which air, at about 140° F., was blown by means of an electric fan. It was found that by crushing the chestnuts before drying the time of the operation could be reduced 4–5 times. After crushing, the drying was completed in 26–28 hours. The dried chestnuts were ground to a meal, the chemical composition of which was as follows: moisture 11·1 per cent, crude protein 6·6 per cent, oil 5·7 per cent, carbohydrates 70·0 per cent, crude fibre 4·3 per cent and ash 2·3 per cent. The boiling of the chestnuts was done every three days throughout the experimental period. The chestnuts were crushed and were boiled for one hour with an equal weight of water. When the boiling was completed the water, then a yellow-grey liquid, was drained off, leaving the nuts soft, but the shell remained hard. Boiled chestnuts kept well for about a week, after which mould developed.

The third treatment consisted of soaking crushed chestnuts in cold water for at least forty-eight hours before feeding. After that time the smell suggested that some fermentation had taken place. The yellow-greenish liquid was drained off. The soaked chestnuts did not keep well, mould starting after less than two days. On the other hand, when after draining off the liquid, clean water was added, the chestnuts kept in good condition for at least one week. It is of interest to note that soaking of whole, uncrushed chestnuts for a week in cold water did not seem to have any effect on them.

As the time progressed the horse chestnuts, which were stored spread on a concrete floor in the piggery, deteriorated fairly rapidly. Towards the end of the experiment more than half the nuts had to be rejected at crushing. Evidently, unless dried by artificial means the chestnuts will not keep for any considerable time.

Soon after the commencement of the experiment it was found that the shell of the chestnuts is unpalatable to the animals, and that they refused to eat it. After a fortnight it was decided to feed both the boiled and the soaked chestnuts without the shell, and the nuts were decorticated before feeding. The shells were removed by hand, a rather tedious and time-consuming operation.

Experimental.—The method of individual feeding was adopted. Five treatments were introduced, and five pigs, one allocated to each of the treatments, formed an experimental block. Three blocks were operated, that is, each treatment was replicated three times. All the five pigs constituting a block were litter-mates and as alike as possible at the beginning of the experiment. The pigs used were home-bred Large White, and were put on the experiment when about fourteen weeks old.

The five experimental treatments were as follows: (1) Control—normal fattening diet. (2) Negative control, similar to diet 1, except that 10 per cent of the wheat feed was left out from the mixture, and the pigs were fed to a scale reduced by 10 per cent. (3) As diet 1, but with 10 per cent of the wheat feed replaced by dried horse chestnut meal. (4) As diet 1, but with 10 per cent of the wheat feed replaced by boiled horse chestnuts (decorticated). (5) As diet 1, but with 10 per cent of the wheat feed replaced by decorticated horse chestnuts soaked in cold water for at least forty-eight hours before feeding.

The composition of the control diet (1) was as follows (all parts by weight): wheat feed 40, barley meal 28, ground oats 20, fish meal 10, dried grass 2. The meal mixtures were all mixed by hand in the piggery.

The animals were rationed according to a scale for fattening pigs recommended by the Pigs Experiments Coordination Committee[4], except for the pigs on treatment 2, which were fed at a level lower by 10 per cent. The meal was weighed out and fed twice daily in the form of a wet mash, 3 lb. of water being allowed for each pound of meal. The boiled and soaked chestnuts were added directly to the troughs and were well mixed with the meal. The chestnut meal formed a constituent of the meal mixture fed to pigs on treatment 3.

The experiment commenced on December 17, 1942, and was continued for 133 days (nineteen weeks).

Results and discussion.—The results of the feeding trial are summarized in the accompanying table.

The small number of animals used in this test does not allow final conclusions to be drawn, but the following observations may be made.

	Treatment				
	1	2	3	4	5
Average initial live weight	70·3	68·0	70·7	68·0	75·0
Average live weight gain	149·0	141·3	125·7	138·0	147·3
Average daily live weight gain	1·12	1·06	0·95	1·04	1·11
Pounds of food per one pound live weight gain	4·0	3·7	4·6	4·0	4·1

When horse chestnuts, either in dried form, or boiled, or soaked, are added to a fattening mixture at a rate of 10 per cent of the ration, the pigs consume them, and no toxic effects are observed. The food value, of such chestnuts is, however, very small, and it appears that the low nutritive value is mainly connected with the unpalatable, thick, hard shell which the pigs tend to reject provided they could separate it from the rest of the meal. When the shell is removed, the decorticated soaked chestnuts are able to replace satisfactorily 10 per cent of wheat feed in a balanced fattening meal. Boiling the chestnuts before feeding reduces their nutritive value, some of the nutrients being dissolved and drained off with the liquid. Even after boiling the shell remains objectionable to the animals.

Although, as we have found in a post-experimental period, the amount of decorticated and prepared chestnuts can be increased to about 20 per cent of the ration, none of the methods of preparation merits recommendation for practical application. The difficulties in storing raw chestnuts and the labour and cost of preparation prohibit the feeding of chestnuts to pigs.

The dried horse chestnut meal has no nutritive value, and the animals show a definite dislike to the meal mixture containing it. Whatever the nutritive value of the nut itself, the presence in the meal of the ground shell completely hides it. The question of the nutritive value of decorticated, but otherwise untreated, horse chestnut meal remains open.

CONSERVATION OF HUMUS IN TROPICAL SOILS

By DR. A. SREENIVASAN

Institute of Plant Industry, Indore

THE part played by humic manures in soil processes and in plant nutrition, both as a source of mineral elements and by improving the physical condition of the soil, is well known. The advantages of properly devised rotational systems of cropping in soil husbandry are also established by both practice and experience. It is therefore reasonable to expect results of great economic importance by a combination of rotational cropping with humic manuring. The permanent manurial small plots at the Institute of Plant Industry, Indore, afforded an opportunity of studying the relative importance of humic manures and crop rotation on the conservation of soil properties. These plots, sixteen in number, have, since 1933, been receiving annual surface dressings of farm compost, farmyard manure and municipal compost, all at ten tons per acre, and have been under a four-year rotational cropping with (i) cotton, (ii) sann (*Crotalaria juncea*), ploughed in and followed by wheat, (iii) ground nut, and (iv) jowar (*Andropogon sorghum*); one set of four plots (including a control unmanured plot) being under a particular crop during a season. The plots treated with the different humic manures, while yielding more or less alike from year to year with all the crops, had frequently given more than double the yields of the untreated plots.

Surface (0–6 in.) and subsoil (6–12 in.) samples were taken from each of these plots during flowering time in October and examined individually in the laboratory. Some of the results obtained are discussed here. Only the average values for corresponding plots are given in Table 1, there being no appreciable difference in the results for plots under different crops.

It will be observed that the surface layers of the manured plots contain a lower percentage of clay and fine silt as compared to the untreated plots. This is no doubt due to the greater infiltration, on account of openness of soil, in these cases. It is well recognized that cultivation or addition of organic matter increases pore space and decreases volume-weight, and that these are followed by increased infiltration capacity. From the data, however, it is seen that the differences in pore space or volume-weight between the untreated and manured plots are only small. Likewise, the values for moisture-holding capacity are about the same for all the soils, thus suggesting that, with crop rotation, even unmanured plots do not deteriorate in physical properties. It should be remembered that these plots receive a green manure of sann once during every complete rotation of four years and that, besides, another legume is included in the rotation.

The most significant contrast between the unmanured and treated plots, accounting for the difference in their productivity, is revealed, however, from an examination of the values for carbon and nitrogen which shows that the latter contain much higher percentages of nitrogen and, especially, of carbon. This enrichment of organic matter is also reflected in the higher structural coefficients of these plots[1].

That the building up of the soil organic matter through humic manures has steadily increased with time can be seen from Table 2, which gives the percentage increases, over untreated plots, in carbon and nitrogen at different periods for all the humic manured plots (averages).

The high values obtained for carbon and nitrogen during July is obviously due to the plots having received the manures during the preceding month.

Exposure of humus-rich soil, sampled in February 1943, for nearly six months, which included the hot summer months of April–June, had resulted only in a loss of 4·2 and 10·1 per cent of carbon from the surface and subsoil samples respectively, the corresponding losses from the untreated plots being 7·9 and 5·1 per cent; but during this period there was considerable fixation of atmospheric nitrogen with both soils. Further work is in progress to study the influence of different environmental factors on the carbon and nitrogen status of these soils.

The conservation of carbon and nitrogen through humic manuring is by no means unfamiliar in temperate regions. Thus, from a study of the changes in soil composition caused by fertilizer treatments in the Broadbalk manurial plots at Rothamsted, it is recorded that on the farmyard manure treated plot

TABLE 1. INFLUENCE OF MANURING AND CROP ROTATION ON SOIL PROPERTIES.

Treatment	Depth (in.)	Clay + fine silt (per cent)*	Pore space (c.c. per 100 c.c.)†	Volume-weight (gm. per 100 c.c.)†	Moisture content of saturated soil (per cent)†	Coefficient of structure	Carbon (per cent)*	Nitrogen (per cent)*
Farm compost	0–6	45·6	57·3	140	56·8	0·66	0·89	0·151
	6–12	47·1	59·1	142	58·5	0·69	0·72	0·139
Farmyard manure	0–6	46·6	57·0	142	57·2	0·69	0·84	0·140
	6–12	49·8	55·7	140	58·0	0·70	0·70	0·132
Municipal compost	0–6	48·4	55·9	142	57·3	0·68	0·78	0·130
	6–12	47·6	57·0	140	57·2	0·70	0·72	0·129
Untreated control	0–6	50·0	56·4	143	55·5	0·60	0·59	0·118
	6–12	48·6	57·8	145	56·1	0·60	0·60	0·113

* On oven-dry basis. † On air-dry basis.

there has been a marked gain in both carbon and nitrogen, especially in the earlier years, the soil now containing more than twice as much organic matter as most of the other plots[2]. Similar results on the increase in nitrogen content of farmyard manure plots cropped continuously with wheat and barley have been observed at Woburn[3]. An improvement in the nitrogen status of soils following the addition of farmyard manure to soil even under tropical conditions has recently been shown by Dhar and Mukerji[4]; according to these authors, the carbonaceous substances from the decomposition of organic manures assist in the fixation and conservation of soil nitrogen[5].

On the other hand, it has been frequently contended that every soil, depending on a number of complex and interlocked factors, mostly climatic, has more or less definite organic matter and nitrogen status and that it is, therefore, scarcely worth while to attempt to maintain the soil nitrogen and organic matter above certain percentages[6–9]. The foregoing observations would suggest, however, that by the application of bulky organic manures these constituents can, within limits, be maintained at higher levels and within an expense that may be justifiable in terms of crop rotation. In analysing the results of fifty years of field experiments at the Woburn Experimental Station, Russell and Voelcker have recently come to the conclusion that soil impoverishment under continuous cropping can best be prevented by a combination of farmyard manure with crop rotation[3].

Humic manures are generally slow-acting and have, in consequence, a much higher residual effect as compared with the immediately available commercial fertilizers. With a deep-rooted crop such as cotton, therefore, their application may not be advisable if their full value is to be utilized. But if they are applied to a previous surface-rooted crop in the rotation they will not only benefit that crop but also have their characteristic effect on the deeper soil layers by the time the turn of the cotton crop comes. This fact has been fully borne out by the work at Indore, where (i) successive application of compost has given consistently high yields with cotton over a period of years, and (ii) in rotation experiments, compost application to the previous crop has always benefited the succeeding cotton crop.

TABLE 2. PERCENTAGE INCREASE IN CARBON AND NITROGEN OVER UNMANURED PLOTS.

Period of sampling	Carbon		Nitrogen	
	Surface soil	Subsoil	Surface soil	Subsoil
October 1940	42·4	18·3	18·6	17·7
July 1942	64·1	33·3	69·6	43·5
February 1943	50·8	33·9	35·4	19·6

Agronomic practice hitherto has largely been directed towards determining what manures should be applied to each particular crop. The experience with the permanent manurial plots, however, suggests that it would be more beneficial to manure with the object solely of building up the general fertility of the soil, so as to take care of all crops in the rotation and thus conserve the natural resources of the soil and, in some measure, even improve on them.

RELATION BETWEEN BODY-SIZE, WAKING ACTIVITY, SIZE OF EYE-BALLS, AND THE ORIGIN OF SOCIAL LIFE IN THE PRIMATES

By PROF. M. F. ASHLEY MONTAGU

Hahnemann Medical College and Hospital, Philadelphia

THE demonstration of significant, that is to say functional, interrelations between characters of size, morphology, physiology, and social behaviour has not, to my knowledge, hitherto been made for any group of the order of Primates, including man. In the present communication I should like to report what seems to be the invariable association of four such distinctive characters which are operative throughout the order.

Commencing with an examination of the most primitive members of the order of Primates, the lemurs, we find that they fall into two groups; one is practically completely nocturnal in its habits, sleeping by day and spending most of its waking hours during the night, while the other is mainly diurnal, being almost entirely active by day alone. Like most Primates, all lemurs are arboreal creatures, though the larger lemurs, particularly of the genus Lemur, spend a good deal of time among the rocks. Now, it is a striking fact that the lemurs of small body-size are all, unexceptionally, the most definitely nocturnal in their habits, while those of larger size are almost entirely diurnal. This in itself is an interesting association. It would also appear that the small nocturnal lemurs have larger eyeballs than the larger diurnal lemurs. Finally, the small nocturnal lemurs live either in pairs or in single families, while the larger diurnal lemurs tend to live in small groups which contain the members of at least one other family.

Since the lemurs represent the most primitive, as well as the oldest, type of Primates, being, indeed, best regarded as a relict group, it may reasonably be assumed that they preserve the social habits of even earlier ancestral Primates. The point is not very important, but it is worth mention because it is known that the earliest Primates were not much larger than small rats, and from this—together with the evidence cited in this communication—it may be inferred that they were probably nocturnal in their habits, and lived in pairs or single families, as do the closely related primatoid menotyphlous insectivores (for example, Tupaiidæ) to this day.

The evidence provided by the lemurs suggests that small arboreal Primates are better able to survive when they are active at night than they are when they are active during the day. Large eyes provide them with the necessary visual power to pursue their nocturnal activities, and these activities can most effectively be pursued in a solitary manner or in pairs or in small family groups. These seem to be the facts for the lemurs.

The reverse conditions seem to be equally closely connected. Now, what are the facts for the remaining suborders and families of Primates? Are these facts or is this association of conditions corroborated by the conditions existing in any other group of Primates? It may be said at once that the evidence is strikingly corroborative, and where it is exceptional, very enlightening.

The exception to the rule of having all four variables positively correlated is provided by a single family among the Platyrrhini or Old World monkeys, the Hapalidæ, consisting of the marmosets and tamarins. These animals are about the size of a small squirrel, but they all have small or medium-sized eyes, are diurnal in their habits, and are said to live in pairs or in single families. The two important correlations are here (1) between body size and the habit of living in pairs or in single families, and (2), between diurnal activities and small or medium-sized eyes. I shall return to a discussion of the significance of these facts presently. Meanwhile, we must be grateful to Nature for providing us with exceptional cases, for these often serve to throw light on the relative importance of variables which are otherwise too closely correlated to lend themselves to the necessary separation and analysis.

Finally, and most significantly, among the ten genera of the family Cebidæ (South American monkeys) embracing some ninety-three different species, the species of smallest size (embracing ten species) all belong to the same genus Aotes, the douroucoulis or night-monkeys. These are the only monkeys, among the Cebidæ, which have large eyes, are nocturnal in their habits, and live in pairs or in single families. They are about the size of a squirrel.

All other Primates of the platyrrhine and catarrhine series are of relatively large body-size, with small or medium-sized eyes, are diurnal in their activities, and live in communities or bands. (By a community or band is meant a group consisting of the members of two or more families.)

We have here, then, an almost perfect correlation between (1) body-size, (2) kind of primary social group, (3) waking or sleeping activity habits, and (4) size of eyes.

Small Primates are likely to have large eyes, to be nocturnal, and to live either in solitude, in pairs, or in small family groups. Large Primates are likely to have small or medium-sized eyes, to be diurnal, and to live in bands or communities.

The conditions existing among the marmosets indicate that when small Primates are diurnal their eyes are small or of medium size, and that they retain their habit of living in pairs or in single families.

It need scarcely be pointed out here that even a complete positive correlation does not necessarily imply a causal relationship between the variables found in association. Such an association may be due to still other conditions, and it is a safe general rule to assume that this is the case until every effort has been exhausted to prove it so. In the present case, in virtue of the nature of the data, such attempts to prove the existence of significant additional conditions are not readily feasible. Our task must therefore lie in an attempt to educe the order of most probable relationship existing between the four variables we have noted. In this we are greatly assisted by the apparently aberrant conditions found among the marmosets. From the latter it appears that body size is directly associated with small social groups limited to a single pair or a family, while size of eyes is most directly associated, as would be expected, with type of waking activity.

To conclude, then, the evidence suggests that increase in body size (and, presumably, weight) may have been a potent factor in releasing the early Anthropoidea from their crepuscular habits, by enabling them to hold their own against most aggressors, and that this together with the potentialities released by the assumption of a diurnal life led to the development of more extended social relations with animals of their own species. It is perhaps worth pointing out that this is not a speculation, but an interpretation of facts to which a high degree of probability is attached.

A fuller account of these findings will be published in the *American Anthropologist*.

ADVERTISEMENT OF PROPRIETARY MEDICINES

"MASS OBSERVATION" has issued the results of their investigation among their national panel of voluntary informants of the attitude of these informants to patent medicines. These informants do not represent a typical cross-section of the population, but the majority of them are dissatisfied with the present position and ask for further Government control of the price, sale and advertisement of such products, because they make exaggerated claims, play upon the fears of illness and prevent people from going to a medical man, so that illnesses which might be recognized early, and arrested, become chronic. These informants do not, on the other hand, wish to see medically approved remedies removed from the market.

Emphasis is given to this report by an annotation in the *British Medical Journal* (Sept. 25, 1943, p. 398) which discusses the experiments performed by Ivy, oback and Stein (*Quart. Bull. Northwest Univ. Med. hool*, 16, 298; 1942) with 'Carter's Little Liver ills'. Using dogs, these workers injected the pills solution in alcohol intravenously, or in solution in ater intraduodenally, giving the equivalent of 2–4 ills per dose. None of the doses produced any gnificant increase in the flow of bile or of the essure inside the gall bladder. The makers of arter's Little Liver Pills' claim, says the annotation, at the pills flush the poisons out of the system ith two pints of bile and that they are the standard edical formula for waking up the liver. Each pill, ys the *British Medical Journal*, is said to contain ·25 gr. of Curaçao aloe and 0·0625 gr. of Podophylli sin. The annotation adds: "These experiments int to a distant goal—the authoritative study of e pharmacological action of all proprietary prepara- ons and the unbiased publications of the results".

That the Newspaper Proprietors' Association is ive to the importance of control of the advertise- ent of proprietary medicines is shown by the follow- g rules governing such advertisements which have een unanimously adopted at a recent meeting of the ssociation. They appear in the *British Medical ournal* of October 9, p. 462.

(1) No advertisement will be accepted by the ewspapers represented in the Newspaper Proprietors' ssociation which offers for sale to the public any edicine or treatment which is directly or by implica- on held out in terms calculated to lead to the belief hat the medicine is effective in: (*a*) The treatment f Bright's disease, cancer, tuberculosis or con- umption, diabetes, epilepsy, fits, locomotor ataxy, ataract, glaucoma, disseminated sclerosis, osteo- rthritis, spinal, cerebral and venereal diseases, lupus, paralysis or for preventing any of those ailments.) For the cure of amenorrhœa, hernia, blindness, heumatoid arthritis, or any structural or organic ilment of the auditory system. (*c*) For procuring e miscarriage of women. (*d*) For the treatment of abits associated with sexual indulgence or for any lment associated with those habits.

(2) No advertisement will be accepted from an lvertiser who by printed matter, orally, or in his lvertisement undertakes: (*a*) To diagnose by orrespondence diseased conditions or any particular seased conditions in a human being or to receive om any person a statement of his or any other erson's symptoms of ill-health with the view of lvising as to, or providing for, the treatment of ich ill-health by correspondence; or (*b*) to treat y correspondence any of the ailments specified in ection 1 above.

(3) No advertisement will be inserted containing testimonial other than one limited to the actual iews of the writer, or any testimonial given by a octor other than a recognized British medical ractitioner unless it is manifest that the doctor is ot a British doctor of medicine.

(4) No advertisement will be accepted containing lustrations which are distorted or exaggerated in ich a manner as to convey false impressions.

(5) No advertisement will be accepted which in ny way may lead persons to believe that the product commended emanates from any hospital or official urce or is other than a proprietary medicine adver- sed by a particular manufacturer for the purpose ecified, unless the advertising agent submitting the py declares that the authority of such hospital or fficial source had been duly obtained.

These rules are now in operation in all the London morning, evening and Sunday newspapers and all advertisements will, in addition to conforming to these rules, be submitted to medical scrutiny and the product to chemical analysis if it is considered necessary. This is the first time that the national newspapers of Great Britain have unanimously laid down and insisted on a standard of control over statements and claims made in advertisements.

A SYNTHESIS OF A 42-CHROMOSOME WHEAT

THE solution of the jigsaw-like puzzle of the origin of the 42-chromosome wheats of the 'vulgare' or bread-wheat type has been attempted by various methods. A recent endeavour to synthesize a bread-wheat by crossing *Triticum turgidum* ($2n = 28$) with *Aegilops speltoides* ($2n = 14$) adds a new piece to the puzzle (W. P. Thompson, E. J. Britten and Jean C. Harding, *Canad. J. Res.*, C, 21, 134; 1943). It is generally agreed that the monococcum group of wheats ($2n = 14$) has the chromosome sets *AA* and the majority of the emmers ($2n = 28$) the genoms *AA* and *BB*, while all the bread-wheats have the constitution *AA BB CC*, the *C* sets being derived in some way from some species of the genus Aegilops, one of the species of which, *Aegilops cylindrica*, seems to have the genoms *CC DD*. The new species is the result of an attempt to repeat the hypothetical events in the origin of common wheat by first crossing one of the emmer section with a species of Aegilops with 14 chromosomes, and then producing the fertile amphidiploid by doubling the number of chromosomes with the aid of colchicine.

The new type has leaves with a single line of long hairs on the summit of each ridge, a hollow stem, the collar at the base of the spike open, rounded U-shaped glumes with wide truncated 'shoulders' and weakly developed keels, all of which are regarded as typical bread-wheat characters. In the bearded varieties of the vulgares, the awns are shorter than those of the emmers and in this character too the amphidiploid is near the bread-wheats. The teeth at the apex of the glumes are short and blunt as in most varieties of *T. vulgare*. The hairs of the brush at the apex of the grain are intermediate in number and length between the emmers and the vulgares. The rachis, however, is fragile, with a disarticulation which is characteristic of the emmers, and the slender rachis segments have their tops wider than the bases, as in the emmers.

In undoubled F_1 plants, the pollen mother-cells showed 1–3 trivalents in more than 80 per cent of the cells, while 5 or 6 bivalents occurred in 26 out of 57 cells, and 4–7 bivalents in 51 out of 57 cells. In the pollen mother cells of the amphidiploid plants the greater majority showed a few unpaired chromosomes as well as associations of three or four. 75–95 per cent of the pollen appeared good and about three to a dozen grains were set in most heads. Back-crossing with *T. vulgare* and *T. Spelta* was possible both with the amphidiploid as the male or the female parent, but the resulting grains were badly shrivelled and germinated poorly. Of the 8 backcross hybrid plants obtained, 5 had 42 chromosomes and the remaining three 41, 40 and 39.

Thus it can well be said that a wheat-like species which in most essentials is a vulgare type has been synthesized: a new piece has been found for the puzzle, though whether it has been inserted in the correct place remains to be seen. There occur a number of perplexing difficulties which the authors do not set out. Thus, although they do not find as great a proportion of bivalents as Jenkins in the pollen mother-cells in their undoubted F_1, it is still high. This, together with the report of seven perfectly normal bivalents and fairly regular tetrad formation in the hybrid *Aegilops speltoides* × *T. monococcum* (Chizaki, 1932) and the 6–7 bivalents reported by Lilienfeld and Kihara (1934), as usually occurring in the hybrid *A. speltoides* × *T. Timopheevi* (*AA GG*), are difficult to reconcile with the assumption that *A. speltoides* contains the *C* sets of chromosomes. Again, the authors make no mention of the number of nucleoli in their new wheat. In both *A. speltoides* and the emmer wheats there are four nucleoli (Pathak, 1940), so that the resulting amphidiploid will probably have 8 nucleoli, whereas true vulgare wheats have only 6. It may well be that the new type in reality has the constitution *AA BB A′A′* rather than the elusive *AA BB CC*.

B. C. S.

ROOTS OF MOUNTAINS

PROF. BENO GUTENBERG, of Pasadena, California, has been doing a considerable amount of work recently on problems connected with the earth's crust immediately beneath high mountains. He has investigated in great detail the structure of Southern California as it may be interpreted in the light of data from 'near' earthquakes. In a recent paper he summarizes our present knowledge (much of which is due to himself) concerning the roots of mountains throughout the world ("Seismological Evidence for Roots of Mountains", by Beno Gutenberg. *Bull. Geol. Soc. Amer.*, 54, 473–498; April 1, 1943).

Prof. Gutenberg states that all results based on the study of seismograms of nearby continental earthquakes indicate that below the sediments is a layer in which the velocity for longitudinal waves is between 5·55 and 5·60 km./sec. It is considered granitic. Below it, intermediate layers showing higher velocities definitely show regional differences. Their lower boundary is the Mohorovičić discontinuity, below which a material, probably ultra-basic, in which the velocity is about 8·0 km./sec., is found nearly everywhere. The velocities through the granitic as well as those through the ultra-basic layers are the same in different regions, within ± 0·4 km./sec.

The maximum thickness (60–70 km.) of the 'continental layers' above the Mohorovičić discontinuity thus far has been found under the southern Alps and about the same under the Sierra Nevada. Whereas the root of the Alps seems to be due mainly to an increase in the thickness of the granitic layer, present indications are that the granitic layer under the Sierra Nevada extends roughly down to the same depth (about 20 km.) as generally in Southern California; mainly the intermediate layers are thicker under the Sierra. In other continental regions, the Mohorovičić discontinuity is in general at a depth of about 50 km. under areas with moderately high mountains, and of about 40 km. near oceanic coasts. An especially low value of 30 km. has been found in New Zealand. Under the Atlantic and Indian Oceans these layers have probably an even smaller total thickness and are practically absent under the Pacific Basin. The boundary of the crystalline crust is within the ultra-basic material.

DESIGN OF ALTERNATORS FOR SWITCHGEAR TESTING

A PAPER by V. Easton (*J. Inst. Elec. Eng.*, 90, Pt. 2, No. 16; August 1943) deals with some of the factors which affect alternator design. Due to the rapid growth of interconnexions on many systems during the last fifteen years, the greatly increased voltage and current likely to be caused by a fault at many switching stations has necessitated the design of circuit-breakers of larger capacity, and in turn this has made desirable improved facilities for technical investigations and for proving the rating of the breakers. The paper discusses the mechanical and electrical factors which affect the design of alternators supplying power for switchgear testing, and a review is made of several methods of increasing the output of such alternators, the merits of each being critically examined.

In the section on electrical design the author deals with reactance, time-constants and damping circuits, recovery voltage, and speed of plant and losses. The section on mechanical design covers slot conductors, end windings, foundations and couplings. Finally, the author discusses various methods of increasing output and considers the effect of external reactance, increased initial voltage, shorter duration of test, super-excitation, and parallel operation of plant. All the methods to increase output may be applied to existing plant, the most suitable probably being an increase in the initial voltage or a reduction in the duration of the test period. Super-excitation may also be adopted, but if complete neutralization of the stator M.M.F. is desired the super-exciter set must be of large capacity, probably designed for a high voltage, and the arrangement may be relatively inefficient.

The method to be adopted for an extension to existing plant may be influenced by the arrangement of the sets with which it is required to run in parallel, but for a new installation some degree of super-excitation should be provided. The choice lies between a large excitation set capable of maintaining the stator current at the initial value and a small set with controlled switching to eliminate the D.C component of the stator current and permit the switch under test to be opened a few cycles after the master switch closes. Technically, the former scheme is the more satisfactory from the point of view of the flexibility of the testing procedure, the severity of the test conditions, and ease in interpreting the results. Economic considerations may, however, be of sufficient importance to offset the complications and the reduction in the severity of the test introduced by controlled switching.

RIVER CONTROL IN BRITAIN

AMONG the terms of reference of the Centra Advisory Water Committee was a consideration of what enactments, if any, were required to co-ordinate the various river interests, and the desirability of constituting new river authorities with responsibility for some or all of the functions now exercised by existing bodies. There were found* on examination of the subject, a great many bodies each exercising limited control generally of one or ther aspect of river water. Pollution, drainage, sheries, inland navigation, tidal navigation, orts, water supply, sewage disposal, etc., each as for most rivers a separate supervising body. he complex administration for this diversity of losely interrelated problems has led the Committee o suggest means of more closely co-ordinating dministrative control.

---

* Ministry of Health. Third Report of the Central Advisory Wate Committee: River Boards. (Cmd. 6465.) Pp. 77. (London: H.M Stationery Office, 1943.) 1s. 3d. net.

The defects of the present system are most apparent s regards the mitigation of pollution, a problem in hich the local government areas bear no relation to atershed areas. Thus there is a patchwork of conrol, actuated by varying standards of purity, over he same river. Moreover, an overlapping of functions n this and other problems does not encourage ficiency and smooth working. In certain river terests no authority is directly concerned with menities and public use. Again, an authority conrned only with drainage may well interfere with nderground water resources in other parts of the ver valley, and there may be considerable divergence etween the interests of bodies charged with conrvation of fisheries, use of tidal waters, sewage disarge and industrial work.

The Committee finds, however, that the principal efect of the existing system is not the overlapping nction, nor the possibility of conflict between inrests, but the fact that no single body is charged ith the duty of co-ordinating various river interests, r the duty of weighing fully all questions under view and so ensuring that the river water is used the best advantage of all concerned. It suggests, herefore, the formation of new river boards in place f certain of the existing bodies. Tidal waters, except s regards pollution, should be left under the authority f navigation and other similar authorities. Probably he same restriction should apply to inland navigation hich, generally speaking, should be left under the lministration of existing authority. The administrave area of each of the new boards should be a atershed area in the case of the larger rivers, or vo or more watershed areas grouped together.

A map of the twenty-nine suggested river boards attached to the report, which concludes with nsideration of constitution and finance.

A SYNTHESIS OF NEW WORLD ARCHÆOLOGICAL FINDS

O many local publications have been appearing lately, some of considerable interest, that it is relief to turn to a work of synthesis. A recent ublication of the American Philosophical Society *roc. Amer. Phil. Soc.*, "Recent Advances in merican Archæology", 86, No. 2; February 10, 43) is extremely interesting in that it attempts to ing up to date, or rather to the end of 1942, the ore important archæological discoveries in the New orld. There are fourteen articles, and it is to be gretted that space will only allow of one or two of ese to be referred to.

Archæologists interested in Maya problems will rn at once to the first article, but the second, hich deals with Eskimo archæology and its bearing the problem of man's antiquity in America, is also great interest. A new site has been examined, d the culture there discovered (Ipiutak) does not adily fit in with the accepted chronological sequence cultures, although it is clearly related to that known as the 'Old Bering Sea', and may even be earlier in date. Much material is turning up in the Lake Baikal region in northern Asia, and this has been dated as Mesolithic to Neolithic. The finds are definitely earlier than the Bronze Age Glazkovski and Tiverski cultures. These early northern Asian finds recall intimately the early stages of Eskimo cultural development. Indeed, it would seem certain that the two cultural areas can be equated. But neither near Lake Baikal nor in early Eskimo sites have such earlier types of tool as the Sandia or Folsom points come to light, and in the Baikal district only one example recalling the Yuma point has turned up. The Yuma point occurs in American sites later in time than either the Sandia or the Folsom, and it would thus appear that there were folk in America at an earlier date than this Lake Baikal complex, which gave rise afterwards to the Eskimo migrations into the New World. Whether the Sandia and Folsom cultures represent the results of earlier migrations into America from northern Asia—perhaps of upper palæolithic date—remains to be proved. The upper palæolithic finds eastward of Lake Baikal are at present too scanty to furnish any evidence. The very early discoveries at the Sandia Cave may not yet be assimilated by every archæologist, as they are fairly recent news. Articles both on Sandia Cave and on the problem of the Folsom and Yuma points can be read in these *Proceedings*.

A long account of the burial of an early American magician, illustrated by no less than three plates in colour, is of considerable interest.

The above notice mentions only a few of the articles which help to bring up to date the recent archæological discoveries, and the whole forms an important symposium for anyone interested in the archæology of northern America. M. C. B.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, November 13

BIOCHEMICAL SOCIETY (in the Department of Organic Chemistry, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 11 a.m.—Discussion on "The Tetrapyrrolic Pigments".

At 11.15 a.m.—Prof. D. Keilin, F.R.S.: "Properties and Function of Natural Tetrapyrrolic Compounds".

At 12.10 p.m.—Prof. H. Munro Fox, F.R.S.: "Varieties of Hæmoglobin".

At 1.45 p.m.—Mr. R. Hill: "Tetrapyrrolic Compounds in Plants".

At 2.35 p.m.—Dr. E. F. Hartree: "The Constitution of Catalase".

At 3.15 p.m.—Mr. J. R. P. O'Brien: "The Metabolism of Blood Tetrapyrrolic Pigments".

At 4.30 p.m.—Dr. C. Rimington: "The Porphyrinopathics".

Monday, November 15

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 3 p.m.—Mr. Otto Popper: "The International Regime of the Danube".

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 7.15 p.m.—Dr. O. P. Einerl: "Present and Future Application of Light Alloys".

Tuesday, November 16

ROYAL SOCIETY FOR THE PREVENTION OF ACCIDENTS (BIRMINGHAM AND DISTRICT INDUSTRIAL COMMITTEE) (in the Council House, Birmingham), at 10 a.m.—Conference on "Industrial Safety" (to be opened by Mr. Geo. Tomlinson, M.P.).

At 10.30 a.m.—Sir Wilfrid Garrett: "The Future of Accident Prevention".

At 11.45 a.m.—Mr. W. Higgs, M.P.: "Economics of Safety".

At 2.15 p.m.—Dr. J. M. Davidson and Mr. S. H. Wilkes: "Chemical Hazards—New and Old".

At 3.15 p.m.—Mr. A. P. Young: "Education and Propaganda".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. R. M. Titmuss: "Social Environment and Eugenics".

INSTITUTION OF CIVIL ENGINEERS (ROAD ENGINEERING DIVISION) (at Great George Street, Westminster, London, S.W.1), at 5 p.m.—Mr. H. J. E. Carter and Dr. A. R. Lee: "The Use of Cold and Wet Aggregates in Bituminous Construction for Roads and Aerodromes".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Henry Dale, G.B.E., P.R.S.: "Progress in the Treatment of Infections", 3: "Present Developments".*

INSTITUTION OF ELECTRICAL ENGINEERS (WIRELESS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "The Role of Ultra-High Frequencies in Post-War Broadcasting" (to be opened by Mr. K. I. Jones and Mr. D. A. Bell).

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (at 16 Princes Gate, South Kensington, London, S.W.7), at 6 p.m.—Demonstration of Eastman High-Speed Camera, Type III, with Films Taken on It.

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the SHEFFIELD BRANCH OF THE INSTITUTE OF WELDING) (at 198 West Street, Sheffield 1), at 6.30 p.m.—Mr. H. F. Tremlett: "Metallurgical Aspects of the Welding of Hardenable Alloy Steels".

CHEMICAL SOCIETY (in the Lecture Theatre of the University, Teviot Place, Edinburgh), at 7 p.m.—Prof. M. Polanyi: "The Strength of Carbon Bonds".

Wednesday, November 17

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. Stuart Hibberd: "The Coming-of-Age of the B.B.C.".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Sir Edmund O. Reale: "The Contribution of Geological Surveys to Colonial Development".

ASSOCIATION OF CZECHOSLOVAK SCIENTISTS AND TECHNICIANS (SECTION OF MECHANICAL AND ELECTRICAL ENGINEERING) (at the Czechoslovak Institute, 18 Grosvenor Place, London, S.W.1), at 5.15 p.m.—Mr. J. Pochobradský: "Aurel Stodola—the Teacher, the Scientist, the Man".

Thursday, November 18

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. E. J. Bowen, F.R.S.: "Wave Mechanics and Colour of Organic Compounds".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir James Jeans, O.M., F.R.S.: "The Methods of Modern Astronomy", 3: "Physical Astronomy".*

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. G. W. Warren: "High Vacuum Technique".

Friday, November 19

PHYSICAL SOCIETY (OPTICAL GROUP) (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 2.30 p.m.—Discussion on "The Measurement of Aberrations, with Special Reference to Photographic Lenses" (to be opened by Mr. T. Smith, F.R.S.)

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Prof. C. E. Inglis, F.R.S.: "Gyroscopic Principles and Applications" (Thirtieth Thomas Hawksley Lecture).

INSTITUTE OF PHYSICS (LONDON AND HOME COUNTIES' BRANCH) (at the British Institute of Radiology and Rontgen Society, 32 Welbeck Street, London, W.1), at 6 p.m.—Prof. W. V. Mayneord: "The Physical Principles of Radium Therapy".

Saturday, November 20

BRITISH RHEOLOGISTS' CLUB (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 2 p.m.—Commander C. F. Goodeve, F.R.S.: "Rheology and Naval Problems".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PRINCIPAL OF THE OPENSHAW MUNICIPAL TECHNICAL SCHOOL—The Director of Education, Education Office, Deansgate, Manchester 3 (November 18).

HORTICULTURAL INSTRUCTOR (MALE)—The Clerk to the Somerset County Council, County Hall, Taunton, Somerset (November 19).

EDUCATIONAL PSYCHOLOGIST (WOMAN)—The Secretary, Education Offices, County Hall, Northallerton, Yorks. (November 20).

HEAD OF THE ELECTRICAL ENGINEERING DEPARTMENT—The Secretary, Robert Gordon's Technical College, Aberdeen (November 20).

LECTURER with good workshop experience for the PRODUCTION ENGINEERING SECTION of the Mechanical Engineering Department—The Organizer for Further Education in Rugby, College of Technology and Arts, Eastlands, Rugby (November 20).

SPEECH THERAPIST—The Director of Education, Education Offices, Nelson Square, Bolton, Lancs. (November 20).

ASSISTANT (temporary) to teach MATHEMATICS and other JUNIOR ENGINEERING SUBJECTS—The Principal, County Technical College and School of Art, Newark, Notts. (November 22).

LECTURER IN THE MATHEMATICS DEPARTMENT—The Principal, Heriot-Watt College, Edinburgh (November 22).

ASSISTANT LECTURER IN GEOLOGY—The Registrar, University College, Nottingham (November 22).

ASSISTANTS (temporary) to RURAL LAND UTILIZATION OFFICERS in certain parts of England and Wales (candidates should have a sound knowledge of general agricultural practice)—The Ministry of Labour and National Service, Central (Technical and Scientific) Regis
Alexandra House, Kingsway, London, W.C.2 (quoting Reference
E.A.738) (November 23).

ADVISER IN AGRICULTURAL CHEMISTRY—The Registrar, The Uni
sity, Manchester 13 (November 23).

ASSISTANT (temporary) IN AGRICULTURE at the Somerset F
Institute, Cannington, near Bridgwater—The Clerk to the Some
County Council, County Hall, Taunton (November 24).

EDUCATIONAL PSYCHOLOGIST (full-time) to be responsible for
direction of the Child Guidance Clinics of the County Borough
Lincoln and Grimsby—The Director of Education, City Educat
Office, 4 Lindum Road, Lincoln (November 26).

INSPECTOR FOR MATHEMATICS—The Clerk to the Board, Cen
Welsh Board Offices, Cardiff (November 30).

HEADMASTER OF REPTON SCHOOL (candidates must be gradu
of a university in the United Kingdom or elsewhere in the Bri
Empire, but need not be in Holy Orders)—The Clerk to the Govern
102 Friar Gate, Derby (November 30).

REGIUS PROFESSOR OF ZOOLOGY at Glasgow University—The Pri
Secretary, Scottish Office, Fielden House, 10 Great College Str
London, S.W.1 (January 17).

SENIOR TECHNICAL OFFICER, TANK TECHNOLOGY—The Ministry
Labour and National Service, Central (Technical and Scient
Register, D. Section, Alexandra House, Kingsway, London, W.
(quoting Reference No. D.634).

IRRIGATION ENGINEER by the Government of Northern Rhodesi
The Ministry of Labour and National Service, Alexandra Ho
Kingsway, London, W.C.2 (quoting Reference No. E.784).

FULL-TIME LECTURER IN BIOLOGY, mainly for Zoology, which m
be offered to Degree standard—The Registrar, Municipal Coll
Portsmouth.

ASSISTANT ENGINEER for the Sudan Government Railways—
Ministry of Labour and National Service, Central (Technical
Scientific) Register, Alexandra House, Kingsway, London, W.
(quoting Reference No. E.783).

SPEECH THERAPIST (WOMAN)—The Chief Education Officer, Edu
tion Offices, 215 High Street, Smethwick 41, Staffs.

LECTURER IN STRUCTURAL ENGINEERING at the Constantine Te
nical College—The Director of Education, Education Offices, Wo
lands Road, Middlesbrough.

TEACHER OF MATHEMATICS AND ELEMENTARY SCIENCE up to Sch
Certificate Standard for Service students at the Victoria Institut
The Secretary for Education, 4 Copenhagen Street, Worcester.

DEAN OF ENGINEERING COLLEGE, Baghdad—The British Cour
3 Hanover Street, London, W.1 (endorsed 'Baghdad').

DIETICIAN (non-resident)—Matron "R2", Staines County Hosp
Ashford, Middlesex.

DEPUTY DIRECTOR OF MANUFACTURE AND PLANNING in the A
nautical Stores Division under the Government of India—The Minis
of Labour and National Service, Central (Technical and Scient
Register, Alexandra House, Kingsway, London, W.C.2 (quo
Reference No. C.1943A).

HEADMASTER FOR THE TECHNICAL SCHOOL OF THE ROYAL AIRCR
ESTABLISHMENT (candidates should have academic qualifications
the standard of a University Degree in Engineering, preferably Hon
and some practical engineering and teaching experience)—The Minis
of Labour and National Service, Central (Technical and Scient
Register, Section D, Alexandra House, Kingsway, London, W
(quoting Reference No. D.700).

SENIOR DIETICIAN (WOMAN) in the Ministry of Food (candid
should possess a Pure Science degree and a Diploma in Diete
recognized by the British Dietetic Association)—The Secret
Central (Technical and Scientific) Register, Ministry of Labour
National Service, Alexandra House, Kingsway, London, W
(quoting Reference No. O.N.F.1425).

TEACHER OF CHEMISTRY for Junior Work in Technical Day Sc
and Industrial and Intermediate B.Sc. classes in the Technical Coll
and a TEACHER OF PHYSICS for Junior Work in Technical Day Sc
and Industrial and Intermediate B.Sc. classes in the Technical Col
—The Chief Education Officer, Education Offices, Park Road, W
Hartlepool.

GRADUATE IN EITHER ENGINEERING OR PHYSICS—The Princ
Stroud and District Technical College, Kendrick Hall, Stroud, Glo

INDUSTRY, RESEARCH AND EDUCATION IN GREAT BRITAIN

IT was one of the merits of the annual reports of the Department of Scientific and Industrial Research that they afforded something of the nature of an annual stocktaking of the research effort of Great Britain. The broad surveys which appeared over the signature of successive chairmen of the the Advisory Council, such as Lord Rutherford and Lord Riverdale, rarely failed to point not merely to achievements but also to directions in which further efforts were required. Although the War has interrupted this fruitful and effective method of encouraging research-mindedness, noteworthy efforts at education have been made in this field during recent months. Debates on economic policy demonstrated a widespread realization in the House of Commons that adequate research must be the foundation of an expanding export trade. Dr. P. Dunsheath's lecture to the Royal Society of Arts on "Industrial Research in Great Britain : A Policy for the Future" is only one of a number of occasions when the whole structure and policy of industrial research has come under review.

Two of the most notable have been the debate on scientific research in the House of Lords on July 15 and 20 and a memorandum on the meaning of research for industry prepared by Sir Harold Hartley. Sir Harold Hartley affirms his belief that industrial research will be the vital factor in determining the future prosperity of Great Britain, and his paper is a plea to industry to accept the help which science can give, and for more industrialists to become research-minded. Despite some outstanding exceptions, there has not been in Great Britain a general appreciation of the value of science in industry, and the expenditure on research has been correspondingly less than in Germany or the United States of America. While British men of science have proved in both the world wars that they can more than hold their own if they are given equal facilities and support, it is impossible to avoid the conclusion that if Great Britain is to maintain its position in the world markets, industry must give greatly increased attention to research as soon as the progress of the War makes it possible. Industrialists should be taking active steps now to organize this aspect of their post-war activities.

This same point is well made in an article on "Foundations of Prosperity" in the *Round Table.* On the technical side, it is pointed out, the failures of industry have come mainly from inadequate support of scientific research and from unwillingness or inability to scrap obsolete plant. That is one reason for the concern which has been expressed regarding recent pronouncements as to the post-war policy of the British motor-car industry ; these statements have aroused doubts as to whether the policy is sufficiently bold and forward-looking and not too tied to pre-war ideas, and reluctant to replace out-of-date plant. As a nation we still present a curious contrast between the most outstanding individual achievement in every branch of science, and a certain suspicion and scepticism concerning the practical value of the scientific approach to industrial problems. There are still managements and workers in the iron and steel and engineering industries whose belief in traditional practices constantly obstructs the use of metallurgical or physical knowledge. Lord Listowel has solid ground for his assertion that full employment and better conditions of life after the War largely depend on our capacity to modernize industrial equipment and processes and to improve the quality and quantity of their output, checking the failure to keep abreast of the times which has characterized some fields of industry.

On this question of obsolescence the *Round Table* article makes the important suggestion that while neither Government nor industry alone can provide a remedy for such technical deficiencies, the Government contribution should not only include raising the standard of education and the promotion of scientific research, in national institutions and in the universities as well as by industrial concerns, but also by devising a system of taxation which will encourage instead of penalize the modernization of equipment. There is no more urgent task in administration than the reform of the principles of inland revenue. Taxation has come to be looked on departmentally as an end in itself, and until that notion is killed and the corpus of statutes and interpretations built up around the income tax over a century, and more is swept away and replaced by principles more in accord with the facts and requirements of modern life, it will remain true that the industries most in need of modernization are those least able to afford it.

Sir Harold Hartley's memorandum is strangely silent on this important point; but, almost simultaneously with the *Round Table* article, the *Economist*, in its centenary number, lends powerful support from another outlook to this plea for reconsideration of taxation policy in regard to obsolescence and development. But all three agree on the importance of the obligation of enterprise in industry, and the words of the *Round Table* article might appear equally well in either of the others: "No Board of Directors in these coming years of stress and reconstruction will be acting in consonance with the spirit and needs of the age, or indeed with the interests of its shareholders, unless it puts back into the business a substantial part of the profits to cover research, development and obsolescence. No organized industry can hope to survive in a world market if it falls behind in these matters or is deluded by the Inland Revenue into the belief that advertisement is more than all these things". The same point was well made by Lord Listowel in the House of Lords in urging a steady increase in existing facilities for scientific research into the post-war problems of industry.

That is Sir Harold Hartley's argument, and his review of the present organization of research in Great Britain leads him to make several concrete suggestions. Even the smallest firm should find a place on its staff for at least one man with a scientific training, and should join the research association for its trade. If there is no research association, the trade association should be urged to approach the Department Scientific and Industrial Research with the view forming a research association. If the trade has r trade association and no research association, firm which do not employ a research staff are recom mended to apply to the Federation of British Indu tries for advice. If they are in a large way of busine they are also advised to consider the establishmen alone or with associated or kindred firms, of a researc laboratory. Closer contact between scientific me in industry and those in the universities, and mo integration between research and development a also suggested, but Sir Harold does not mention thr points which were repeatedly stressed in the House Lords: adequate remuneration of scientific worke in industry; undue reluctance to pool informati on new developments; and the lack of appre ation of scientific methods by the higher Ci Service.

It will be noted that Sir Harold Hartley appea to place his main emphasis on the research associatio but it may well be doubted whether, except with th smallest firms, this is anything like the most effecti line of advance. On this point Lord McGowan spo explicitly in the House of Lords debate. While reco nizing the value of a research association where n single unit is in a position to create a research install tion on a suitable scale, and paying tribute to th work of the Department of Scientific and Industri Research in fostering and encouraging the resear associations, he thought that this system of researc while it may play a large part in future developme has a very long way to go before we can be satisfi that it is up to the standard demanded by mode conditions.

The reasons for this position are readily seen. can be maintained with considerable force of arg ment that the true field of work of the resear associations lies in the fundamental investigations the basic problems of the industry—investigatio which require planning and co-ordinating frequent in relation to the scientific research which is p ceeding at the universities and independent resear institutes. There are practical reasons why t research association can never hope to compe effectively with the research department of an i dividual firm or group of associated firms in t investigation of day-to-day problems and existi processes, in the search for higher efficiency, low costs and new and improved products. Yet it exactly on such problems that some research ass ciations tend to concentrate.

This indeed is only what might be expected. association of firms which individually are n research-minded enough to establish their o research departments, in spite of ample resourc are unlikely to take the long-range view and supp the attack by the research association of the fund mental problems on which eventually the prosper or even the existence of the industry may depen Lord Cherwell's statement showed that the Gover ment is aware of the importance of fundamen research and prepared to extend its support, but t mere formation of a research association is only t irst step in a programme of education and inculcating esearch-mindedness. It may well be maintained that he whole experience of the research association movement would endorse the plea for an investigation f taxation methods in relation to research and evelopment for which the *Round Table* and the *conomist* have so boldly called.

We touch here on questions of industrial structure s well as of the organization of research. In reconsidering the structure of industry, this question of esearch is of cardinal importance in ensuring that spirit and policy of enterprise which are essential oth in private industry and in any form of public orporation which may be established to provide afeguards for the public interest. Unless that spirit ervades the management, no change in organization r structure will avert disaster or provide the developments and technical advances on which a policy of ull employment and rising standards of living can e firmly based.

Sir Harold Hartley's memorandum may well prove timely corrective in some of the discussions at resent proceeding in these fields, and it is the more ncouraging to find that many of his points have een made very forcefully in the House of Lords ebate already mentioned. The emphasis which ord Samuel, Lord McGowan and Lord Dawson of enn laid on the importance of the highest adminis-ative positions in government service being open o technical and scientific men who had shown hemselves fit for such work is indeed relevant. Without support from the top we cannot expect that he resources of research associations or of universities ill be adequate for the tasks which now confront hem.

What is most welcome in the attention now being oncentrated on industrial research is the recognition hat this is a matter in which both industry and overnment have responsibilities. In addition to the esponsibility in regard to the Civil Service and dministration just mentioned, the Government must arry a prime responsibility in regard to the adequate ndowment of scientific research at the universities. ommenting on Sir Harold Hartley's proposals, Sir rnest Simon has stated that preliminary investigaons of a committee of scientific men and industrialists t up by the University of Manchester to consider what developments are needed to enable the University to render services to industry equivalent to those ndered by leading universities in America, indicate hat it will be necessary to think in terms of trebling he Government grant to universities.

Whether or not, as Mr. Bruce Truscot has suggested in his recent book, the universities of Great ritain might make a larger contribution to research om their existing resources, a much larger State ndowment is clearly imperative. Lord McGowan as indicated, however, that here also industry has a g part to play. There can now be little doubt that ose who insisted that it should be a condition of otection under the Import Duties Act that the dustries concerned should pursue an active policy research and development were fundamentally ght. Failure to insist on this, for example, in the iron and steel industry, has clearly been unfortunate, and the record of the Import Duties Advisory Committee is largely one of missed opportunities from which the whole country has suffered.

Lord McGowan made the point effectively in urging this as one reason why industry should play its part in encouraging scientific developments in the universities and technical schools of Britain. He pleaded for industry to play its part by means of financial grants, particularly to ensure that equipment is adequate in quality and in amount.

But this question of closer contact between the industrial and the academic worlds to which Lord McGowan referred touches closely the question of education. Mutual discussion between industry and the academic man of science may be largely profitless if the standard of education in industry is not sufficiently high. The extension of scientific academic facilities and of technical schools is a post-war issue of the utmost importance if Britain is to hold her own and realize the possibilities which greater research-mindedness on the part of industry might put within her reach. Lord Maugham commented trenchantly on the absence of reference to science in the White Paper on Education, and there are few signs that the opportunity which is offered to us by the scientific developments in the Fighting Services and the consequent wider interest in technical science are fully comprehended.

Education, indeed, in its broadest sense, is the key to the situation. The education of the industrialist, for which Sir Harold Hartley pleads, is one line of advance. The education of the Civil servant and the opening of the higher posts in the Civil Service to those trained in scientific research is another, and on this point Lord Cherwell's statement for the Government was hopeful. The extension and improvement of university facilities and of those for technical training at all levels is another, and it is clear from recent statements that have been made that this aspect is being borne in mind. Vital as it may be to effect immediate improvements by all these means, to secure a fuller endowment of research and development work, its adequate co-ordination by administrators imaginatively alive to the issues involved—and that at every stage in industry, from management to the operative—and a personnel technically and scientifically competent, ultimately it is on the educational system of Great Britain that sustained progress depends. To fulfil the manifold requirements, the system must provide the State and industry alike at all levels with recruits equipped to face the tasks of the new age and aware of the scientific and technical factors which enter into its social, industrial, economic and international problems, as well as of the human, moral and cultural values. It is only in this way that industry and State can be directed and staffed by those aware of the vast possibilities of research, competent to plan and to execute an adequate policy of research, and resolute to see that it issues both in greater efficiency in industry and also in the wider and fuller enjoyment by society of the resources which science has put at our command.

SEX EDUCATION AND GUIDANCE

MANY centuries have passed since Alcuin of York wrote that "Since the time of King Aelfwold . . . the land has been absolutely submerged under a flood of fornication, adultery and incest, so that the very semblance of modesty is entirely absent", but variations on the same theme are still played to-day. Since the outbreak of the War, indeed, they have been both numerous and persistent. In part, such dismal wailings may be discounted as the product of present-day tension and upheaval, but after all allowance has been made for this, a nucleus of truth remains. It is a fact that conditions of war almost invariably lead to an increase in sexual promiscuity, and even the least bigoted among us can scarcely fail to be disquieted.

But while it is such war-time behaviour, with its resulting increased incidence of venereal infection, which has at long last been responsible for removing the taboo on public discussion of sex and sexual behaviour, the problem is not in essence a purely war-time one. In the long run, our hopes for the development of a healthy attitude to sex in our society must be based not only on economic and social change, but also on rational and fearless education. The importance of the latter is clearly recognized by the Board of Education, and its recent pamphlet on the subject* will be given a warm welcome by all progressive educationists.

For many years individual education authorities, schools and youth clubs have been undertaking sex education, and some have done excellent work in this field. This is, however, the first occasion upon which the Board has given so clear a lead; and many who were wondering whether or not to go ahead will no doubt do so under this new impetus. It is important that those who do should be very careful, in carrying out this most valuable but rather difficult work, that they adopt methods likely to produce the best results. Not all the efforts in this field in the past have been entirely happy in their conception or fortunate in their results, and thereby the cause of sex education has sadly suffered. It is, therefore, particularly gratifying to note that the Board of Education itself proposes "both to conduct a special course in the near future, which it is hoped may help a number of men and women to assist in local courses, and to deal with this matter where appropriate in other courses that they organise". No doubt advantage will be taken of the experience of those who have for some years specialized in this field, and local education authorities are in fact advised to apply for help to the Central Council for Health Education, which has for some time been providing lecturers, literature, films and general advice.

The pamphlet is in the main based upon the results of inquiries recently made by H.M. Inspectorate, and presents an interesting survey of present practice i this sphere. Apparently, about "a third of th secondary schools in the country make a seriou attempt to give instruction", while "the remainin two-thirds of the schools are about equally divide between those who give slight attention to the subject or avoid it altogether". So far as the elementar schools are concerned, "it would appear that in th areas of approximately half the Local Educatio Authorities in England, and to a lesser extent i Wales, there is carefully planned instruction in a least a few of the schools"; while in other areas "perhaps one-third of the country . . . practicall nothing is done". It is interesting also to observ that "approximately three girls' schools include se instruction in their syllabus for every one boys school"—a conclusion that confirms the strong impression to that effect previously held by those wh have been concerned in this work.

Excellent in quality as much of this work i educationists cannot rest content until the great gap are filled in, and the standard of all such teachin raised to that of the best. The facts gathered b the inspectorate make it very clear that the method adopted vary widely, and perhaps this is well, fc we have as yet insufficient experience to lay dow the law about their relative merits. What does see to be clear, however, is that the instruction shoul be fitted as inconspicuously as possible into th ordinary school routine, and that sex education conspicuous in a school only in proportion to t imperfection. In many places, where the staff fe unable or unwilling to incorporate sex education e their day-by-day lessons, recourse is had to the se vices of the specialist lecturers of the Central Counc for Health Education; but this Council itself recognizes that such a method is very far from ideal an can be regarded only as a temporary expedien This makes it particularly important for local education authorities to arrange courses for their teacher both to provide the non-biologists among them wit the necessary factual knowledge, and to make suggestions about methods of classroom presentatio Apart from courses on biology and health educatio generally, special courses on sex education hav either already been held, or are at present bein arranged, for the teachers of Surrey, Middlese West Sussex and Dorset among the counties; Dew bury, Doncaster and Bristol among the coun boroughs; and an occasional progressive urba district like Enfield. It is also clear, from the conferences which have been held elsewhere, th many more teachers' courses will materialize befo long.

So far as the schools are concerned, the mo important task is the presentation of simple b accurate biological information. "But early instru tion in the physiology of sex is only the beginning sex education in the fullest sense. It should b succeeded at the later end of adolescence by i struction and advice directed to the understandi and control of sexual impulse and emotion, leadi on to the establishment of mutual understanding a respect between the sexes, and, as young manho or womanhood is approached, to an adequate preparation for marriage". The early school-leaving age n Great Britain means that for the great majority of children the schools can do little in this respect, but the youth organizations have a great opportunity. Here the objections to visiting lecturers, which are so potent in the case of schools, scarcely apply, and the usual procedure is for a course of three or four talks illustrated by films to be given by a member of the staff of the Central Council for Health Education. Some idea of the extent of this particular part of the work now going on throughout Great Britain is given by the fact that during the six months of April–September 1943, there have been held 578 such meetings, attended by 16,223 young people.

---

* Board of Education. Educational Pamphlet No. 119. "Sex Education in Schools and Youth Organizations." (London: H.M. Stationery Office, 1943.) 6*d.* net.

The Board of Education pamphlet emphasizes that youth leaders "themselves require more accurate and comprehensive knowledge than they already possess". "To meet this need both local education authorities and the youth organisations are increasingly arranging short training courses in sex education for leaders, or are devoting attention to the subject at their general youth-service courses." A particularly interesting course was that held recently at Horsham. A carefully selected group of leaders attended a residential week-end school, and at sessions attended by the County Director of Education, Medical Officer and Youth Organizer, a team of speakers dealt with many aspects of sex education in youth organizations. It is likely that as a result of the school, a county panel of recognized lecturers will be drawn up; they should be able to carry out much valuable instruction in the youth organizations of West Sussex.

Particularly in respect of sex education in schools, the fear has sometimes been expressed that there may be parental opposition. Figures collected recently show this fear to be quite unfounded. Some schools and education authorities have, before introducing such lessons, circularized parents of pupils and given them the opportunity of withdrawal. Whether in fact this is a wise procedure is a matter of debate, but the numerical results are quite conclusive. Of 320 pupils from a girls' grammar school in Dorset, only two were withdrawn; of 500 in a similar school n Surrey, four; of 550 in a similar school in Kent, none. A boys' grammar school in Lancashire has given such instruction for some years, with never a single withdrawal; of 470 pupils in a similar school n Surrey, the parents of 380 actually wrote to give approval and to enclose a contribution towards the expenses of the lecturer. The story in senior schools s similar. A Lancashire urban district had twenty-one withdrawals out of 936, and a neighbouring county borough but fifteen out of 2,300. There is ndeed a wealth of support for the pamphlet's assertion that "parents welcome any initiative shown by teachers".

Particularly welcome is the Board's recognition, that "the first responsibility rests upon parents to deal with their children's questions from the beginning, as and when they arise, in a natural manner". This, however, raises a serious problem —that of fitting the majority of parents to do so. It is not usually recognized by scientific men that for nine parents out of ten this is at present rendered extremely difficult, even neglecting consideration of emotional unsuitability, by the simple matter of ignorance of the necessary minimum of technical vocabulary.

It is an unfortunate fact that during the last few hundred years the old Anglo-Saxon terms for the sexual organs and the sexual processes have descended far in the social scale, and in many cases have now reached the gutter. Precisely those parents who would be most willing to answer their children's queries will be most reluctant to do so in the only sexual language they know. A warm welcome must therefore be accorded to the pamphlet's suggestion for "The organisation of parents' meetings, with a view to securing their co-operation in anything that is done through the schools, and to helping them in dealing themselves with their own children in this matter". Actual lectures on the physiology and psychology of sex, and on sex guidance to classes of parents, would also seem worth trying. The children's problems are cropping up at all times, and it therefore seems undesirable that in the long run everything should be left to the teacher.

Perhaps the main criticism that can be levelled against this publication is its almost complete scholastic isolation and neglect of the social forces involved as determinants of sexual attitudes and behaviour. The prefatory note refers to "the immediate problem presented by the increased number of young persons who fall victims to the special temptations and circumstances of war-time", and expresses the excellent hope that further efforts will be made "to bring such persons within the influence of the Youth Service". But there is no mystical quality to the phrase 'youth service' which will enable it to conquer its environment. All sorts of social changes will be needed before sex education can yield its fullest fruits. The economic barriers to early marriage must go, and we must so conduct our society that millions of homes are not periodically broken up. Young people must be given some burning sense of social purpose, some feeling that they can be of real service to the community and be valued by it, some belief in a future for which it is worth while to sacrifice immediate sensual gratification. Sex education cannot thrive *in vacuo*. It must be sex education for a particular social setting.

Some educationists may feel a certain disappointment at the benign impartiality of the Board in this pamphlet, and may regret that more detailed and positive suggestions are not given as to teaching technique. But this would be a matter not so much for a pamphlet as for a book, and even a book could do little more than skim over the surface of the many problems involved. There is, moreover, a real danger in the presentation by a Government department of too detailed suggestions, the danger of stifling local initiative and experiment; and if this pamphlet does nothing more than to stimulate such experiment and initiative, the Board of Education will have rendered a great service.

RECENT ADVANCES IN VIRUS RESEARCH

Virus Diseases

By Members of the Rockefeller Institute for Medical Research: Dr. Thomas M. Rivers, Dr. Wendell M. Stanley, Dr. Louis O. Kunkel, Dr. Richard E. Shope, Dr. Frank L. Horsfall, Jr., Dr. Peyton Rous. Pp. ix+170. (Ithaca, N.Y.: Cornell University Press; London: Oxford University Press, 1943.) 12*s*. net.

THE time is not yet ripe for the production of a comprehensive text-book on virus diseases because virus research is proceeding at such a pace that many accounts are outmoded almost by the time they are published. It is unfortunate that the book under review has been given the title it bears for it deals with very few virus diseases, and those from strictly limited viewpoints. It is a collection of six Messenger Lectures delivered at Cornell University by six experts in different branches of virus research. The founder of the series prescribed its title as "The Evolution of Civilization", and the appositeness of the subjects chosen cannot be questioned. Each author naturally lays particular emphasis upon the more recent developments in his own special field. A more appropriate title would have been "Recent Advances in Virus Research".

No individual can hope to keep abreast of all the literature concerning viruses, yet the interrelationship of recent discoveries in human, animal and plant virology makes it imperative for the research worker to have some acquaintance with the whole. This book is admirably adapted to restore that sense of perspective which is so easily lost during the pursuit of knowledge along a single narrow track, partly because of the breadth of the field covered but even more because each lecturer has such a highly individual outlook and method of approach.

The first chapter, by T. M. Rivers, serves as an introduction by first discussing immunity in virus diseases from a general point of view. Rivers corrects the commonly held, but erroneous, idea that virus immunity differs fundamentally from immunity in other infections; special techniques of study have had to be evolved but only because of the peculiar nature of the infecting agents. The nature of viruses is indeed the *leit motif* of the whole book, and Rivers uses the recent advances of knowledge about vaccinia virus to show that, however simple some of these agents may be, the larger ones like vaccinia may have a structural, chemical and antigenic complexity comparable with that of many bacteria. He concludes that infective agents of fundamentally different natures are to be found amongst the viruses.

In the second chapter, W. M. Stanley deals with viruses at the opposite end of the scale of complexity, namely, those plant viruses which can be obtained, pure, in crystalline form. He is especially concerned with alterations of chemical structure as a key to virus mutation. The idea of mutation being dependent upon modification of chemical structure is no new one, but the crystalline plant viruses have, for the first time, opened up the possibility of direct experimental attack on the problem. The examination of eight strains of tobacco mosaic virus for only five amino-acids and sulphur revealed significant differences, and it is obvious that this line of attack promises fruitful results. It is a long cry yet to the purposive creation of virus variants for prophylaxis by chemical manipulation, but the author envisages the possibility and describes his own attempts to this end by which he has reduced the virulence of a virus for one host species while leaving its virulence for another unchanged.

Chapter 3, by L. O. Kunkel, is devoted to the importance of finding new hosts in virus research, and the thesis is supported by a wealth of illustrations drawn from recent research. Chapters on swine influenza by R. E. Shope and human influenza by F. L. Horsfall give fairly comprehensive accounts of these diseases and are to some extent mutually complementary. Unlike the swine disease, human influenza is not a clinical entity; the term embraces a number of conditions, and Horsfall follows the usual classification into pandemic, epidemic and endemic forms. Research has, perforce, been mainly concerned with the epidemic form because the etiological agents of the other two are still unknown, and the facts thus far garnered have raised as many problems as they have solved. Human influenza was the subject of a recent monograph by Burnet and Clark, and, while Horsfall covers much of the same ground and gives an admirable summary and critical appraisement of the present position, the limitations imposed by a lecture have prevented such exhaustive treatment as was given by the Australian authors. Shope is fortunate in having a much more circumscribed field to survey He gives a detailed account of his own researches which have gone far towards the solution of the epidemiological puzzles presented by the swine disease, namely, the whereabouts of the virus between epizootics, the reason for seasonal incidence, and the means whereby wide dissemination occurs in a very short time. His discovery of helminth intermediate hosts of the virus has led him to a new, unorthodox conception of swine influenza epidemiology, which excludes direct transmission as a major factor and postulates the seeding of a herd without any chronological relationship to the onset of an outbreak The epidemiological patterns of swine influenza and some forms of the human disease are so similar that Shope's work is bound to provide a stimulus for further research on the latter along unorthodox lines.

In the last lecture Peyton Rous gives a masterly exposition of the relation of viruses to tumours The list of tumours in which a virus has been proved to be the actuating cause is not a large one and does not include any mammalian malignant growth, but there is no tumour for which any other actuating cause has yet been discovered. The author emphasizes that the chemical and physical carcinogenic agents are in an entirely different category—he terms them provocative carcinogens—for, once they have provoked malignant potentiality into activity their role is ended, they do not increase in quantity as the growth enlarges and they have no effect in determining the kind of tumour which arises. There is much indirect evidence that viruses may exist and multiply within the cells of a tumour from which no virus can be isolated. Especially significant are the cancers which often arise within the benign rabbit papilloma, which is known to be caused by a virus; virus mutation is suggested as the likeliest explanation, and a rereading of Stanley's lecture with the tumour discussion fresh in mind cannot fail to prove stimulating.

He would be a dull virus researcher who could read this book without feeling an urge to get back to hi laboratory.

WILSON SMITH.

METEOROLOGY AS A CULTURAL SUBJECT

Ways of the Weather

A Cultural Survey of Meteorology. By Dr. W. J. Humphreys. Pp. v+400. (Lancaster, Pa.: The Jaques Cattell Press, 1942.) 4 dollars.

DR. W. J. HUMPHREYS is well known among meteorologists the world over as the author of a number of valuable books on meteorology. In his latest book Dr. Humphreys aims at providing “an easy stairway, or even a gentle ramp for some, in this corner of the temple of knowledge”. Here and there he discusses aspects of the weather which find little or no mention in the ordinary text-book, while the sixteen chapters of this book will give the reader a sound basis for building a fuller structure of detailed knowledge.

The aim of the book is to treat meteorology as a cultural subject, which presents a myriad facets of interest to the intelligent man, entirely apart from any application to the business of life, though these applications are indicated in the course of the book. Technical expressions are almost entirely avoided, even when they might have facilitated the discussion of the point at issue.

Methods of observation are described in an early chapter, and subsequent chapters deal with the disribution over the earth and at different heights in the atmosphere of temperature, water vapour, pressure and wind, the travel of sound through the ir, meteorological optics, electrical phenomena and hunderstorms. The function of the sun as the source f all atmospheric energy is brought out clearly. One of the best parts of the whole book is that which deals with the formation and classification of clouds; this is illustrated by an extremely well-selected and beautifully reproduced series of cloud photographs.

The author draws no distinction between cloud droplets and rain-drops except that of size. It would have been worth while at this stage to give some ndication of Findeisen's theory, according to which the distance through which a drop of water can fall through the air before it is completely evaporated is proportional to the fourth power of its initial radius. Thus, if the relative humidity of the air beneath a loud is 90 per cent, a cloud droplet of initial radius 0 μ will only fall through a vertical distance of about in. before being completely evaporated; a cloud droplet of initial radius 100 μ will fall through a distance of about 500 ft. before complete evaporation ccurs; any droplet having a radius appreciably greater than 100 μ will fall to the ground as rain. This fixes 100 μ as a rational and useful limit between loud and rain. The reader would also have been nterested in Bergeron's theory that the formation f rain-drops large enough to fall to the ground is due to the fall of ice crystals through clouds of liquid roplets. The medium in which the water drops are suspended must be supersaturated relative to ice, so that rapid condensation takes place on the ice crystals, with consequent drying out of the medium and evaporation of the water drops. The ice crystals grow nd fall to the ground, being melted into rain-drops n the way down.

I have few faults to find with Dr. Humphreys' ook. It has achieved its aim to a remarkable degree, and while avoiding difficult concepts has contrived o give the reader a clear picture of many of the phenomena of weather. The author has a scholarly mind, and a pleasing way of quoting passages from the Bible or from the Latin and Greek classical authors when, and only when, they illustrate the point under discussion. Thus on p. 227, in the course of a discussion of St. Elmo's fire, we find the following passage from Cæsar's Commentaries: “In the month of February, about the second watch of the night, there suddenly arose a thick cloud, followed by a shower of hail; and the same night the points of the spears belonging to the Fifth Legion seemed to take fire”. After a careful perusal of this book, the reader will have acquired some idea of what makes the wind blow, why the trade winds blow from the east, why it is generally colder on a hilltop than in the valley, why a rainbow is never seen at noon on the equator, why ‘Aurora's fingers’ are rosy; and if he has sorted out the appropriate factors, he will also have learned how to select the ideal site for a home, either for himself or for his apple trees.

One question recurs to me, as it always does after reading any book which aims at presenting a complex subject in simple terms: Will the reader of this book of nearly 400 large octavo pages really be as non-technical as the author assumes? Is that reader in fact helped by the statement made on p. 128, concerning the molecules in air, that “if 500,000 people were each picking them out at the rate of 100 per minute, day and night, it would take them 1,000 years to accumulate enough to make a volume of the air we breathe as large as the head of a pin”. Would it not be better to give the number of molecules in, say, a cubic centimetre or in a cubic inch, possibly supplementing it by the statement that it is a ‘whale’ of a large number? D. BRUNT.

MOUSE GENETICS

The Genetics of the Mouse

By Dr. Hans Grüneberg. Pp. xii+412+14 plates. (Cambridge: At the University Press, 1943.) 30*s*. net.

THE study of inheritance must always be more laborious than most other forms of biological investigation which concern themselves with only one phase of an animal's whole life-history. It is therefore not surprising that there are only very few animals, and not many more plants, about the genetics of which we know enough to feel confident of having even a crude picture of their commoner modes of variation. Among these animals the mouse holds a very important place. The rapidity of its breeding, the comparative ease of maintaining colonies, and the large number of variations bred by ‘the fancy’, have made it perhaps the favourite mammal for geneticists. It shares, with Drosophila and maize, the distinction of having a ‘hot news’ journal (*Mouse Genetic News*) devoted to the technicalities of its genetics and circulated semi-privately to scientific murophils. A new monograph summarizing the enormous literature which supports the mouse's standing in the world of geneticists will therefore be welcomed, both by specialists, who will find it a convenient summary of their field, and by non-murine geneticists, who want a guide through the tangles of the subject. Both these groups will find Dr. Grüneberg's treatise, with its classified list of 1,141 references, entirely satisfactory for their needs.

“The Genetics of the Mouse” is, however, something more than a merely competent summary of available data. The particular richness of mouse genetics, at its present state of development, lies in its wealth of examples of morphological abnormalities occurring during the development of a mammal, and in this field Dr. Grüneberg is one of the foremost investigators in the world. His account of these aspects of the subject is the fruit of a long and intimate acquaintance with the material, and embodies many original, and to some extent not previously published, observations. It is certain to remain for many years the standard work on the subject.

Grüneberg very justly emphasizes the great interest that many of these developmental abnormalities may have as experimental material for physiological and pathological investigations, in which the purely hereditary side of their behaviour would be of minor importance. His book is, in fact, a storehouse in which biologists of many kinds could find fruitful suggestions for studies in their own fields. The famous example of the pituitary dwarf is an instance which has, of course, already been put to good use by hormone specialists. Similarly, the rodless retina race has been employed in some studies of behaviour, and so have the famous 'waltzer' and 'shaker' strains, though more remains to be done with the numerous pathological variations which are available. There are numerous other types, such as the two forms of hydrocephalus, or the race with a hereditary absence of the corpus callosum, about which we know much less. The extraordinary pathological conditions of the integument in races such as 'naked' and 'rhino', and the lesser abnormalities of hair-growth in the various 'waveds', 'caracul', 'rex', etc., offer another wide field for future investigations; and so do some of the sexual conditions, such as the association of deficient mammary development with hairlessness, the 'imperforate vagina' condition and others. The use of genetical methods in the study of susceptibility to cancer and tumour transplantation in the mouse is, of course, a classical example of such a broadening of the purely genetical outlook. It is the subject of a special section of the book, contributed by two specialists in the field, Drs. Little and Gorer. Unfortunately this is in some ways not so satisfactory as the greater part of the work, perhaps because there is scarcely space to make clear the somewhat complicated situation, or, perhaps, because of war-time difficulties in communication between joint authors on different sides of the Atlantic.

Of all the numerous aspects of biology touched on in the book, that which is closest to the personal interests of the reviewer is the embryological. It would scarcely be possible to better Grüneberg's account of the facts of the development of the various abnormalities; and he can unravel some of the causal sequences involved, such as the consequences of the failure of secondary bone absorption in grey lethals. But on the whole it must be admitted that the genetic abnormalities in the mouse pose many more developmental questions than they answer. Even in so well-investigated a case as the grey lethal, we have no inkling of the relation between the skeletal and the pigmentary effects. Grüneberg, perhaps wisely, makes only a very sketchy attempt to classify the types of developmental abnormality which are encountered. In by far the majority of cases, our knowledge ceases when we have traced the pathological condition back to some developmental process which takes place in a sub-standard way for reasons unknown. In contrast to Drosophila (or plants) there are few cases where one organ is replaced by some other organ properly belonging to another region of the body; there is nothing at all closely corresponding to conditions such as aristopedia bithorax, tetrapter and the rest. Speaking metaphorically, the members of the mouse orchestra do not tend to come in at the wrong time with the right phrase—their fault is a tendency to play out of tune Is this difference connected with a lower degree o functional metameric symmetry in a mammal than in an insect ? Or with a greater elaboration of the evocators or 'switches', which makes it less easy for the wrong key to open the right door ? No answer can yet be given ; that is another, and one of the (to me) most fascinating of the stimulating questions raised by Grüneberg's book.

C. H. WADDINGTON.

KEEPING UP WITH ORGANIC CHEMISTRY

Dictionary of Organic Compounds

The Constitution and Physical and Chemical Properties of the Principal Carbon Compounds and thei Derivatives, together with the Relevant Literature References. In 3 vols. Vol. 1: Abietic Acid—Dypnone. New, revised and enlarged edition. Edited by Prof. I. M. Heilbron and H. M. Bunbury Pp. xvi+1072. (London: Eyre and Spottiswood (Publishers), Ltd., 1943.) £6 6s. net; complete £15 15s. net.

THE original edition of this first dictionary of the kind in the English language was finished at the end of 1937, and it was then hoped to issue revised volumes at regular intervals, beginning in 1939 (NATURE, Nov. 17, 1934; Feb. 29, 1936 Feb. 19, 1938). The outbreak of war interfered with these plans, and in the circumstances it is a remarkable achievement to have produced this new edition of volume 1. The plan of the work remains unaltered and the format is identical with that of the firs edition, except that a thinner paper and narrowe margins have been used. As a consequence, the new edition of volume 1, comprising 1,088 pages, is lighte and more compact than the old one of 726 pages.

The volume has been completely rewritten. The many new entries cover the literature of organic chemistry to the end of 1940, and there are some references to still newer work published in 1941 an 1942; at the same time, certain omissions from the first edition have been remedied. As an illustration of the considerable increase in the number of entries the section from "Carene" to "Carvoxime" has grown from 3½ to 7 pages. In a work of this kin it is particularly difficult to maintain a high standar of accuracy, yet this has been done. It is, indeed something of a feat for a critic to find a formula fc α-cyperone lacking a methyl group, or to discern certain dubiety in the bracketing of carvomenthene with piperitol.

It has not proved practicable under war condition to rewrite volumes 2 and 3. These, of course, ar not so far behind the times as the original vol. 1. As they have been out of print for some time, the are being reprinted with supplementary data co lected since the original publication. Moreove vol. 1 contains cross-references to compounds include in the supplements to volumes 2 and 3. Prof. Hei bron, Mr. Bunbury, and their collaborators have onc more earned the gratitude of the chemical community through their labours in maintaining and improving this invaluable Baedeker of organi chemistry.

JOHN READ.

THE FUTURE OF ANTHROPOLOGY

A CENTENARY meeting of the Royal Anthropological Institute was held on October 30. The first part of the proceedings, at the Royal Society, consisted of addresses on the work of the Institute by Sir John Myres (see NATURE of October 30, p. 493) and on "The Role of Anthropology in Colonial Development" by Lord Hailey. This was followed by a symposium on the future of anthropology, held at the Institute, with the president, Prof. J. H. Hutton, in the chair. Four short papers on different branches of the subject were read, each being followed by a discussion.

It was said that the problems of anthropology are more diversified than those of any other science. Thirty years ago, teachers—notably C. G. Seligman and A. C. Haddon—were still able to survey the whole field, but no one attempts to do that to-day in any comprehensive way. Accessions to knowledge and developments in method have entailed increasing pecialization, and it is now inevitable that different branches of anthropology should be surveyed by different workers. The meeting gave an opportunity of judging how far they have drifted apart, and of assessing the advantages and disadvantages of that process.

The first of the four papers was read by Dr. G. M. Morant, his topic being the future of physical anthropology. Three main branches of the study were istinguished:

(1) Man's place in Nature. It may be doubted whether the further study of living forms—by oologists, anatomists, embryologists or physiologists—will ever throw much clearer light on man's origin, and advances in genetics are not likely to reveal the course of his descent in any detail. More recise knowledge regarding these questions must depend primarily on future discoveries of fossils representing the earliest human and related non-human forms.

(2) The evolution of man judged from his skeletal remains of geological antiquity. Here, again, progress must depend on new discoveries, these being of ar more importance than further speculation regarding specimens already described.

(3) The relationships of populations that have existed since palæolithic times. Methods of interreting the records of series of living people and skeletons have been transformed in the present entury owing to the development of statistical methods and genetics. These necessitate fundamental changes in the classical concept of race in man. It was suggested that two ideas which will have to be abandoned completely are: (*a*) that a race is a group f people separated from all others on account of istinctive ancestry; and (*b*) that analysis of modern populations in terms of 'pure races' presumed to have existed at some earlier time is possible.

Dr. Morant referred next to the provision made for eaching and research in British universities. Before he War, there were in Great Britain three whole-me posts for physical anthropologists—a readership at Oxford, a lectureship at Cambridge, and a lecturehip at University College, London—but no one of hese is actively occupied at present. For several years courses in the subject have been given elsewhere y teachers appointed primarily for other purposes.

Finally, practical applications of the study were discussed. These are concerned principally with: he interpretation of medical and demographic statistics; the provision of equipment for the personnel of Fighting and other Services; the exposure of unscientific racial dogmas.

In his paper on the future of archæology, Prof. Gordon Childe dealt with general aspects of the subject rather than specific tasks which will confront archæologists after the War. Existing human institutions, he said, can only be comprehended in the light of the past, and archæology presents the abstract, and therefore potentially scientific, aspect of human history. The Institute has contributed largely to converting the study into a science in the British Isles.

A workable basis of classification has been established, its three aspects being functional, chronological and cultural. Thanks largely to collaboration with technologists, the functions of nearly all artefacts are now understood. The problems of chronology have also been reduced to order and the framework of a scheme has been set up. New techniques that have emerged in the past two decades—concerned with tree-rings, varved clays and pebble counts—open vistas which must be more fully explored.

The cultural classification is a more recent development. The earlier concept of an evolutionary and linear sequence, which found expression in de Mortillet's system of prehistoric phases and Morgan's stages of social organization, is now abandoned. Culture is now recognized to be adaptation of distinct societies to differing environmental conditions. The change of outlook necessitates re-examination and reclassification of the vast accumulation of prehistoric implements preserved in collections.

The work of classification is so far advanced that sober interpretation may be attempted in the form of generalizing hypotheses which unify a mass of data. Much explanation in prehistory has been undisciplined, such as that which postulated the scarcely credible voyages and migrations of peoples of whom we really know nothing. Theories of diffusion are mythopœic unless they can be substantiated by concrete evidence, such as that provided by skeletal remains or intrusive artefacts.

Archæology is more scientific when it asks not where a society came from but how it attained its peculiar development. New possibilities in this direction have been indicated by the studies of Soviet workers. They involve the total products and refuse of a society which are sampled in the total excavation of domestic sites. The sites should be carefully chosen for the verification of well-considered hypotheses. The methods in question might be extended profitably to cover historical periods. It is absurd that we know more of the domestic architecture of neolithic Thessaly than of Periclean Athens. The approach referred to is not altogether new in prehistory, as it was expounded by Pitt Rivers. Application of the methods to give comparative studies of societies or regions over centuries would go far towards providing a solution of the problem of the nature of progress in material culture.

In his paper on the future study of material culture, Mr. R. U. Sayce discussed principally the developments in museum collections which are most needed. He urged that regional museums, specializing in local cultures, should be encouraged. Some of this kind are already well established in the British Isles and elsewhere. Others should be instituted, such as a museum in Nigeria to illustrate the numerous cultures of West Africa, one in the Sudan and at least one in East Africa. The regional collection should be of vital interest to the people of the country. It helps them to appreciate their past and to gain a wider knowledge of their present condition. It may also foster the development of native cultures. Mr. Sayce stressed the need—so often voiced by anthropologists—for immediate action regarding such matters, since the material is rapidly disappearing.

There should also be more museums having a wider scope at suitable centres in Great Britain, especially in university towns. Useful comparisons may be made between our own craftsmanship and that of peoples in remote parts of the world. Russian museums must have helped to break down psychological barriers between the 'civilized' and 'primitive', and to encourage mutual respect between European and non-European peoples.

We have neglected the study of native arts and crafts. Much remains to be learned regarding the selection and quality of raw materials, the emotional attitudes of the craftsmen, and the efficiency of the implements they use. There is a pressing need, too, for distributional studies. Much work on these lines has been done in America and Africa: in Great Britain we have failed to keep abreast of progress on the Continent. There are few of our own things for which the distribution is accurately known. Field-work at home might deal with such questions as the boundaries of distributions, diffusion in progress, methods by which cultural objects are spread, and factors which hinder their dispersion. Experience gained in examining such problems here would be an invaluable preparation for ethnological work abroad.

The last of the four papers, by Dr. Raymond Firth, dealt with the future of social anthropology. He defined this branch of the subject as the scientific study of human culture. It analyses the nature and meaning of men's rules, conduct and beliefs in different types of society. As world relationships have developed, the scope and methods of the study have tended to change. Anthropologists used to be interested mainly in primitive peoples considered in isolation. With the world-wide extension of trade, political interests and missionary and philanthropic effort during the last century, primitive tribes have lost much of their isolation and many of their ancient customs. The interest of the social anthropologist has therefore shifted towards the study of culture-change, especially the effects of civilization on the comparatively undeveloped tribal societies.

The future will see a still greater interest in social processes and their aims: in how societies change and can be made to change; in what kinds of economic, political and religious organization are most desirable, and how they can best be achieved. After the War, changing conditions will present anthropology with new and more complex problems to study. The peasant societies of Europe and the Far East, as well as those of Africa and the Pacific, will need investigation by experts. At the same time there will be a call for more systematic study of many institutions and beliefs in Western culture. On the practical side, social anthropology may be expected to play a special part in applying its results to colonial problems, though without necessarily subscribing to the colonial idea.

Such future trends will involve more collaboration with other social sciences, and more systematic development of social anthropology itself. More international cross-fertilization of ideas and methods is needed. Planned social surveys can be envisaged, with, say, Chinese, Africans, Americans and Eur peans working as a team, or as a body of adviser dealing with a problem or an area anywhere in th world. Schemes may often be concerned with particular problem encountered in a number societies rather than the intensive study of a sing society. This will mean a more active exchange research workers between countries; more trainin facilities and more research centres, especially i areas outside Europe and America. It should als mean helping the public, by talks and books in no technical language, to appreciate the significance the work of the anthropologist. In time, soci anthropology will be recognized as a necessary aid t the understanding and rational control of man' social life.

The discussions which followed the papers we discursive, as such discussions usually are, but vital issue was raised by Prof. Daryll Forde. H emphasized the need for consideration of the relatio ships between different branches of anthropolog and pointed out that their integration should be th concern of the Institute as a whole. Dr. Firth' comments on this topic must have surprised some his colleagues, since he implied that such integratio is neither logical nor desirable. For him physic anthropology is a branch of biology, archaology subsidiary to history, and social anthropology further removed from either than it is from sociolog There is no reason, he said, why social anthropolog should be considered to have closer ties to physic anthropology than to medicine. These were pr vocative remarks.

Owing chiefly to the limited time at their disposa perhaps, no one of the four readers of the papers ha dealt specifically with the relationships betwee different branches of anthropology, though the referred to this question incidentally. For D Morant, the purpose of physical anthropology is reveal the biological history of mankind, from i source to its latest manifestation in the racial pop lations existing to-day. In his discussion of the lig that the archaologist may throw on the developme of human institutions, Prof. Childe pointed out th there should be collaboration with the physic anthropologist. Their studies have many points contact, and they meet on common ground in co sidering the problem of race and culture. It w also observed that there are intimate relations betwe archæology and the study of the material culture historical times. Mr. Sayce dealt principally wi modern artefacts, but he pointed out that interpr tation of their development and present distributi necessitates study of earlier material. With rega to this point, the attitude of the physical anthrop logist and of the student of material culture is t same. If the one is largely concerned with t bodies of living people and the other with the thin they make, the present is considered by both as t outcome of the past, so that all their problems a viewed in historical perspective. These thr branches of anthropology deal with different kinds subject matter, but the connexions between them a clear.

Group activities of human beings not falli within the scope of the archæologist, and other th those expressed by material articles, have still to taken into account. Dr. Firth defined social anthr pology as the scientific study of human culture different types of society. 'Culture' here was tak to cover 'rules, conduct and beliefs', but not articl produced. The discussion was confined to social processes in existing communities, and nothing whatever was said about any historical considerations. t may be assumed that in dealing with 'culture-change', which was his main theme, Dr. Firth would not consider that the historical evidence of contact between European and non-European peoples in the past few centuries is entirely irrelevant, but he certainly implied that the evidence of earlier 'culture-changes', including all in the archæological sphere, might be disregarded by the student of the modern problem.

If social anthropology is restricted in this way, hen there is obviously a gap in the system. Who is o study the world-wide history and development of social institutions ? British anthropologists of earlier generations supposed that this is the major task of the social anthropologist, so that he would make ontact with the archæologist on one side, and on he other he would interpret existing forms in terms f evidence of a historical kind. Generalizations regarding these matters which were widely accepted t one time have since been discredited. It may be supposed that a revolt against 'evolutionary' theories of social development was one of the factors which made many social anthropologists concentrate on the study of existing societies ; and it may be suggested that neglect of historical evidence makes them ess anthropologists and more students of comparative sociology. This would have been the conclusion of their predecessors.

Another, and more decisive, factor which may be presumed to have disposed social anthropologists of he modern school to neglect historical evidence has been the desire to make their researches applicable immediately to practical affairs. In recent years ppreciation of the value of applications of knowledge gained by students of the life of 'primitive' peoples has been increasing. In his address to the anthropologists at their centenary meeting, Lord Hailey said that those concerned with Colonial ffairs feel that study of the way in which social groups originated has little relevance to administrative problems. But they have far more interest in the recently developed anthropological school which concerns itself not with the origins but with the way n which the groups function. Lord Hailey advocated the encouragement of this school in our universities in the interests of the Colonial Service. But if their numbers and resources are not augmented, there s a danger that all the energy of the academic workers in question might be absorbed in dealing with the practical need. It may be suggested, in the interests of science, that if the Colonial or any ther Government Service expects to receive such ssistance, then it should be prepared to pay for it, either by subsidizing universities for the purpose, or else by founding a State-controlled institute. If his is not done, the gain to the State will be a cultural oss to the country.

The same issue between pure and applied anthropology has affected the physical branch of the subject. Some students of it—particularly in the United States—have devoted themselves to problems having an immediate bearing on practical questions. In so far as such researches are not intended to throw light on any historical topic, it may be questioned hether they can rightly be called anthropological. lternatively, they may be supposed to come within the scope of human or social biology, or human genetics, or eugenics. In Sweden the issue has been resolved in a satisfactory way : "The Swedish State Institute for Race Biology"—to which title "Human Genetics" was added later—was established in 1921. Its first major activity was an anthropometric survey of 47,000 conscripts. The satisfaction of the anthropologist in seeing a type of research which he initiated carried out in such a way must be entirely unqualified.

At the meeting with which this article deals, Prof. Forde remarked that a centenary celebration may be considered as a ritual death and rebirth. It is a time for taking stock of the past and preparing plans for the future. It may be suggested that there are two matters which the Royal Anthropological Institute might well consider at the present juncture. The first concerns the definition of the science of anthropology as a whole, and of the branches into which it can be most conveniently divided in this age of specialization. The relations between these branches might be considered at the same time. The second matter concerns the applications of the science to practical affairs, and the general policy of the academic workers concerned regarding the allocation of their resources to further practical needs, on one hand, and the progress of their 'pure' science, on the other.

GEOGRAPHY AND INTERNATIONAL SETTLEMENT

By W. FITZGERALD
University of Manchester

INTEREST in the contribution of geography to knowledge has been greatly stimulated through the influence of war. It is realized that the organization of the war effort in Great Britain depends on a very careful estimate of the resources of all the belligerent powers. Moreover, in preparation for peace, the planning of community life in its proper relation to environment is now accepted as worthy of serious study. At the next peace conference statesmen will undertake a vast experiment in political geography. The framework of frontiers which they then erect will prove its worth in so far as it meets local needs within the boundary zones and at the same time promotes equilibrium in international relations.

In the application of political geography to the study of international affairs the following arguments, briefly outlined, emerge :

(1) Geography establishes a close relationship between types of human organization and their environments ; and the particular objective of political geography is an investigation of the extent to which the nature of States, together with their organization and interrelations, is influenced by, and adjusted to, conditions of geography.

(2) The political pattern of the world is subject to ceaseless modification, and for two main reasons : (*a*) The factors of physical environment on which the pattern largely depends are themselves subject to processes of change which are beyond man's control. Thus, to take an illustration from the Middle East of the Old World, desiccation of climate in past times had the effect of destroying the prosperity of States, and, indeed, of denuding whole regions of all organized life. (*b*) In the political, as also in the social and economic, evolution of mankind—the adjustment of life in all its varied manifestations—to environ-

ment is itself in process of continuous change. This adjustment is, in part, a conscious selection by man of opportunities offered by Nature. It is not solely a matter of geographical influence, much less of geography acting as an agent of determinism. Man assists in designing his own environment, and does so in the light of experience and of his estimate of the opportunities which the physical environment has to offer. Thus the stage of civilization reached is a factor of primary importance in shaping the character of the adjustment. Moreover, the communities of mankind greatly vary in their methods of response to environment, although care is taken not to attempt a comparison between peoples in respect of their innate capacities. Such an investigation is certainly not for the geographer.

(3) The interrelations of States become ever closer—though not necessarily more sympathetic—as man surmounts the geographical difficulties of distance, climate and terrain. Political isolation is impossible to-day, as all States have been brought to realize.

At times of political re-settlement, such as the period now approaching, the geographical basis of frontiers and their justification receive unusually thorough investigation. It is then realized that the boundaries which divide the sovereign States of Europe are instruments of regional partition which have no sanction in geography. Frontiers in geography are rare, and almost everywhere there is transition from one set of environmental conditions of climate, land-form and vegetation—summarized by Herbertson in the term 'natural region'—to another of contrasted characteristics. Moreover, transition is not confined to the physical environment of man. As all his organized activities—in settlement, economic production, State-building, etc. —are influenced by physical geography, the characteristics of one type of civilization associated with a particular region merge with those of a neighbour-type. Such mergence is at times in defiance of political frontiers which, over long periods, are unable to prevent—though they tend to hinder—the spread of cultural influences from one country to another.

As no sanction for frontiers is found in geography, the term 'natural frontier' cannot claim geographical validity. It is most commonly employed in a military context, and to the soldier signifies a boundary which, of those available, is the most likely to provide an adequate line of defence. Until the advent of air warfare the crest of a mountain-range was considered to be the ideal 'natural frontier'; but configuration is not the only environmental feature which might be the basis of natural divisions. Equally natural would be a line defining the limits of nationality. Similarly, the limit of a coal-field or some other industrial zone is entitled to be termed 'natural'. Obviously, any such line is selected for, and justified by, the particular end which the boundary commissioners have in view, but that is not to say that it is endorsed by geography.

As the world is a whole made up of interrelated parts, political frontiers, however 'natural', are artificial lines of division which obstruct inter-regional co-operation, their purpose being to partition what to Nature is indivisible. Through their influence adjacent peoples are turned away from association with each other, and are led to exaggerate the usually small ethnological and cultural differences which distinguish them. Moreover, as they correspond more with political ideals than with geographica realities they may be opposed to a satisfactor economic and social adjustment of the community t its environment.

In a Europe of rival sovereignties devotion t frontiers arises mainly through lack of confidenc in any safeguard of social and political security othe than military defence; and the defence of frontier is intended to be a guarantee both of the inviolabilit of individual States and of the stability of the politica balance as a whole. There is, however, no possibility of dividing from each other the peoples of th great middle zone of Europe by frontiers which exactl define their limits. The widespread interminglin of populations of various ethnic and cultural origin which is characteristic of European society, ha already occurred before the partition of Europe int nation-States fixed the population of the Continen by restricting inter-regional migration. Furthe there is no geographical correspondence between th distribution of nationalities and the distribution the regions within which population is concentrate The welfare of the Continent depends on an economi integration of its regions, similar to the economi integration which the United States have attained but at the same time the autonomy of Europe's man nationally-conscious communities must be preserve Only on such a basis does European equilibrium see possible.

If ever the European system of sovereign Stat should be replaced by the United States of Europ the nations would relinquish much of their individu claim to sovereignty, while retaining cultural an administrative autonomy. Boundaries would st be required for the purposes of administration, they are required, for example, in the federations the Dominion of Canada and the Union of Sout Africa. Once the idea of national sovereignty removed from the concept of frontiers, they cease be the main source of international dispute, an changes affecting them become matters of compar tively simple local adjustment. The principles which boundary demarcation would then be effecte would have more to do with the economic and soci welfare of mankind than with the claims of nationa ism.

The need of the world is less a partition of terr tories between the Powers according to this or th formula than an ordered redistribution of populati within the habitable regions of the world. T present congestion of certain lands and the emptine of others does not correspond to the distribution the world's potential resources. There are va areas within the temperate and tropical zones t climate, soil and vegetation of which are favourab to human life, but which still lie fallow. Their fro tiers are closed to settlement for a variety of reason among them the desire for racial exclusiveness ar the intention to protect certain economic standar against the intrusion of peoples of low material lev On the other hand, there are large areas of the O World where densities exceed a thousand persons the square mile, and where standards of life a greatly depressed by extreme pressure on the ava able land. Such pressure is, in many instance increasing because of a prolific birth-rate. In cou tries where congestion is very acute, not only intern administration but foreign policy also is affecte and the harmony of international society is enda gered. Unilateral efforts on the part of individu States to ease the situation within their own borde cannot be more than partially effective, and the normal outflow of emigrants in search of new homes is prevented by frontier restrictions, which had become increasingly prohibitive before the War. The settlement of the empty, or half-empty, but habitable lands and a corresponding reduction of density in the congested areas, constitute the supreme task of planning now confronting the world. It is a problem to which the geographers should pay continuous attention.

The demands for 'living-space' raised aggressively by Germany are not derived from an objective study of society and environment. Compared with a number of other countries—some of which she has claimed the right to annex—Germany is not overcrowded. Moreover, it could be shown that the natural endowment of German soil is not inferior to the average for Europe as a whole, and that applied science is capable of raising the productiveness of the more sparsely populated districts of Germany to enable them to support much higher densities without overcrowding.

An unscientific attitude towards 'race', with absurd claims of 'Aryan' superiority and intolerance of their neighbours, combine to explain the German demands for *Lebensraum*. Given the type of mental discipline nculcated by the Nazi creed, such demands are inevitably justified by a philosophy of determinism, which is the sanction of Germany's bid for world hegemony. So is explained the emergence of the pseudo-science of *Geopolitik*, which is little more than the prostitution of the ideas of political geography to the ends of a selfish nation.

It is not on the strictly scientific side of geography —concerned with the accurate location and relaionships of phenomena in terrestrial space—that German education requires fundamental revision. Their cartographical, geomorphological and climatoogical disciplines have nothing to learn from us, and n such respects, it must be admitted, their contribution is not excelled by any other nation. But the Germans have long been under the influence of a mystical conception of the destiny of the Teutonic peoples and of the intention of Providence to grant them a dominating position in Euro-Asia. Their geographical perspective may be unsound; but its error is slight compared with the distortions to which history and anthropology are victims in the hands of Nazi scholarship.

In Great Britain there is little possibility of geographical investigation being tainted with the excesive determinism of the politico-geographical school of Haushofer and his associates. The contacts of British geographers with the Continental philosophers of the subject have shown more appreciation of the nlightened doctrine of Vidal de la Blache—with its insistence on man's freedom of initiative—than of any other. The influence of the German school has been relatively slight; indeed, it is doubtful if the best geographical work in Germany from the ime of Ritter and von Humboldt onwards has been adequately studied in Great Britain. So strong has been the refutation by British scholarship of conceptions of economic and geographic determinism, since they were introduced from the Continent by the historian Buckle and others, that the most distinguished of our geographers cannot be charged with proposing any causal relationship between environment and man's aspirations. (This deserves to be nown so as to correct an impression which may have been left by a contribution to NATURE, **147**, 546; 1941.) There is now the possibility that, in constant danger of the charge of materialism as they are, geographers may omit to state with sufficient confidence their conception of the scope and aims of their subject.

SPATIAL ISOLATION OF SEED CROPS

By GORDON HASKELL

THE sudden increase in the acreage of seed crops in Great Britain has brought with it a number of problems. One of the major problems confronting the seed grower is that of reducing to a minimum the amount of contamination of one crop by pollen from an adjacent one.

There are two methods of tackling this. Zoning is now in force for Chenopods, namely, sugar beet, garden beet and mangels, and is shortly to come into force for Brassicas in the Essex seed-growing areas. The second and more usual way of reducing cross-pollination is by spatial isolation, that is, by isolating the crops at certain guaranteed distances from each other. The following account is a survey of recent investigations to determine the safe isolation distances for the vegetable seed crops of Great Britain[1].

Bees are the chief agents of dispersing pollen of *Brassica oleracea* plants, and wind also carries the pollen of kale and kohl-rabi. This necessitates keeping crops of any two members of the same Brassica group[2] at a considerable distance apart. A spatial isolation of two miles is common, and sometimes only one mile for cabbages and kale. Recent experiments at the John Innes Horticultural Institution[3] indicate that under natural conditions no crossing, or perhaps slight, occurs beyond 80 ft. intervals between radish plots. The usual isolation is not less than 40 rods. Tedin[4], working in Sweden, investigated the danger of crossing in turnip seed production. At 27 yd. between crops he obtained a 1 per cent contamination, and there was no perceptible fall in this value for wider separating distances. Tedin decided that the wind was responsible for carrying this small amount of pollen and that a certain number of insects making long flights could also have transmitted it.

With the exception of the broad bean, the Leguminosæ do not require large isolation distances. Soy beans give between 1–2 per cent natural cross-pollination in the field. But crossing between plants of alternate rows is only 0·16 per cent[5]. The recent work of H. Crebert[6] has shown that broad beans undergo 7 per cent outcrossing in the field and breeders in Great Britain experience 5–10 per cent natural crossing in their crops. Evidence of the correct spatial isolation is not available. Cross-pollination of french beans is effected by thrips, which often occur inside the flowers[7]. Barrons[8], working in Alabama, found that at 9 yd. apart there was only 2·63 per cent natural crossing in the common bean. In England seed growers consider that in most varieties of beans the cross-pollination is negligible; seedsmen do not generally ask their growers to isolate fields of different varieties. Peas are considered to be self-fertile and only a short distance is required to protect them against crossing. A separation of crops by 40 rods assures complete elimination of cross-pollination.

Investigations on outcrossing among members of the Umbelliferæ lag behind those of other groups. It is customary to allow half a mile between different varieties of carrots, but there seem to be no definite figures available for other Umbelliferous crops. Parsnip varieties are usually isolated from each other although pollination within the umbel seems to be the rule; it is also customary to isolate celery and parsley varieties. It is therefore surprising to find so little evidence on spatial isolation of these important crops which include herbs of economic importance such as dill, fennel, carraway and anise.

Cucumbers under field conditions undergo 65–70 per cent natural cross-pollination[9]. A spatial isolation of at least 40 rods, or even more, is necessary to eliminate outcrossing between plots of different cucumber varieties. There is little information available concerning the requisite isolation of marrows.

Lettuces have been the subject of a number of investigations. Thompson[10], working in America, grew lettuce plants side by side without protection from insect visitors. He placed the plants "just far enough apart so that the lateral branches of the seed stalks did not touch". Under these conditions there was 1·33–6·22 per cent outcrossing. Under normal field conditions, therefore, the value would be much less. This supports the practice of British growers of lettuce seed crops who do not subscribe to isolation. The sunflower is generally regarded as a cross-pollinated plant, bees acting as the major contaminating agents. Putt[11] has found the amount of natural crossing is *c.* 70 per cent. Satisfactory isolation distances are so far not reported. Information on the spatial isolation of salsify, scorzonera and chicory is lacking. Although endive is a cross-pollinated plant, there has been little research to determine either the extent of outcrossing or the necessary spatial isolation.

Although the tomato flower is a splendid example of a self-pollinating floral mechanism, even this vegetable is not immune from a small amount of outside contamination. Under field conditions there is 2–4 per cent contamination between rows[12]. More recently Currence and Jenkins[13] have shown that 24 ft. between varieties is sufficient to reduce contamination to a negligible amount. Paschenko, who has made a notable contribution to the literature of floral morphology in the tomato, believes that thrips and not wind are the responsible transmitting agents.

The beets, besides the enforced zoning schemes, require isolation to keep varieties in a pure state. The ordinary beetroot is wind-pollinated, although pollination by insects is also possible. Thrips are important pollinating agents of sugar beets. Increasing the distances between plots definitely reduces the danger of crossing. Beyond about 2½ furlongs there is very little contamination, although it is known that the wind carries beet pollen over a distance of more than two miles. In Great Britain commercial practice requires an isolation of 1,000 yd. between the various crops, but "it became increasingly difficult to obtain isolation"[14]. Hedges definitely act as screens and quite considerably lessen crossing between two plots; there is a definite relationship between the height of the hedges and the reduction in outcrossing. Spinach flowers are wind-pollinated, but there are no satisfactory figures available concerning its isolation. Canadian growers allow at least a quarter of a mile between spinach seed fields and try to keep them out of the path of the prevailing winds[14].

All varieties of onions intercross, so that it is necessary to give a spatial isolation of *c.* 40 rods between plots. Insects normally carry out pollination although wind can transmit onion pollen. Canadian growers consider that half a mile is satisfactory, particularly if there are natural barriers such as a adjacent orchard. Similarly it is customary to giv leeks an isolation distance of 250 yd. But furthe investigations on these two crops would be welcome

Although not a major vegetable seed crop of Britain, sweet corn is gaining in popularity. Wind an gravity are the chief agencies in disseminating swee corn pollen. Haber[15] has shown that "the degree o contamination varied with the distance from th source of contamination". Contamination is eliminated with a separating distance of more than 23 rods But there is a record of a blackbird, which had flow four or six miles from the last maize field it ha visited, that carried the pollen on its plumage. Tree are useful in reducing contamination from nearb fields. A grove of trees four rods wide between field eliminates cross-pollination[16]. Canadian growers us a spatial isolation of one mile and preferably with natural barrier, and in the United States the lega spatial isolation is 40 rods between varieties.

OBITUARIES

Prof. W. M. Tattersall

WALTER MEDLEY TATTERSALL, who died o October 5, was born on November 8, 1882, the eldes of a family of eight. He was educated at Liverpoo College and the University of Liverpool, where h studied under Herdman, and he graduated wit first-class honours in zoology at the age of nineteen He won a research scholarship at Cambridge an looked forward to the opportunity of working ther as a postgraduate student, but he was obliged t abandon his intention owing to the sudden death o his father. He took an appointment as naturalist i the Irish Fisheries Department in 1902, and here as one of a small band of enthusiasts under th inspiring leadership of E. W. L. Holt, he assisted in th exploration of the rich deep-water fauna on th south-west of Ireland. It was during these year that he first began his studies of the Crustacea Throughout his life he maintained his interest in thi group of animals, and our knowledge of them ha been greatly extended by the remarkable series o papers he wrote.

In 1909 he succeeded W. E. Hoyle as director o the Manchester Museum, where, in addition to hi museum duties, he acted as tutor at the Universitie of Manchester and Sheffield to classes arranged b the Workers' Educational Association and regular took parties of students to Port Erin for courses i marine biology. He obtained his D.Sc. in 191

During the War of 1914–18 he enlisted as a private in the Royal Garrison Artillery and saw service in Flanders and France. He was wounded and gassed in 1917, and later received a commission; but he never afterwards enjoyed robust health and for the last ten years of his life he suffered acutely from diabetes.

In 1922 Tattersall was appointed professor of zoology and comparative anatomy at University College, Cardiff, a post he held throughout the remainder of his life. Starting with only a single post-intermediate student, he and the able staff he gathered around him succeeded in building up a flourishing school of zoology, and shortly before the present War he had sixteen honours and nine research students, with sixty students in the final class. As a teacher of zoology Tattersall had outstanding qualities. With a broad and comprehensive knowledge of his subject he combined the gift of inspiring others with his own unquenchable enthusiasm, and by his simple unassuming ways he won the devotion of his students. He insisted on the importance of field work, and for a long series of years he regularly took a party of students to Loch Ine in Co. Cork. Last May, the twenty-first anniversary of his appointment at Cardiff was commemorated, a celebration attended by 121 of his old students, while eighty others sent cables and telegrams of congratulation.

In the course of his busy life at Cardiff, Tattersall was for seventeen years a member of the Court and Council of the National Museum of Wales, and many universities called on his services as external examiner. He edited the natural history volume of the Glamorgan County History and served as president of the Cardiff Scientific Society. At University College he was for a time dean of the Faculty of Science and latterly deputy principal. He had been a member of the British Association for more than thirty years, and there was scarcely a meeting he did not attend. He travelled with the Association to Australia and Tasmania, to Canada and to South Africa, and went o India as delegate to the Indian Science Congress. He served as secretary and recorder to Section D, of which in 1939 he was president-elect.

Tattersall will long be remembered as our foremost authority on certain groups of Crustacea—principally he Isopoda, Amphipoda, Tanaidacea, Mysidacea and Euphausiacea. He was the ideal systematist, careful, horough and methodical in everything he underook, and with that well-balanced outlook that sees in taxonomy a means to an end rather than the end itself. Above all he was a prodigious worker. Busily occupied throughout his life with important educational work, he always found time to continue his personal studies, and the steady stream of valuable papers which he contributed over a span of forty years is a monument to his industry and ability. Reports by him are to be found among the results of almost every marine biological expedition which has set out from Great Britain during the present century, and from all parts of the world collections were sent to him for examination and description. He was a naturalist in the best sense of the term; interested as much in the development, habits and distribution of species as in their identification, and taking immense rouble, as in his latest paper on the relict fauna of Ennerdale Water, to find a logical interpretation of his results. In addition to his work on Crustacea he made important contributions to our knowledge of the Cephalochorda and Enteropneusta; he was the first to trace the life-history of the periwinkle, and he described the very remarkable larvæ of the starfish Luidia.

At the beginning of the present War he had just completed the manuscript of a volume on the Mysidacea for Bronn's "Thierreich", and since then he finished a report, to which he had devoted four years of work, on a large collection of Schizopods from the American Museum of Natural History. There are hopes that the Ray Society monograph of British Mysidacea, on which he was recently engaged, is sufficiently advanced for publication.

Tattersall married Olive Selden Attride in 1916, and much of the fruitful work that he was able to undertake in his long years of illness is due to her unremitting care and devotion. As a student of science she was able to give him very substantial assistance, and she herself drew nearly all figures which illustrate his papers.

In Great Britain Tattersall seems not to have been appreciated at his full worth: a foreign zoologist once asked me why it was so. Perhaps it was partly because of his unassuming modesty, his lack of 'push' and hatred of self-advertisement, his contentment in the interest of his subject and in the satisfaction that comes of honest work faithfully performed. But in part, I believe, it was because with new methods of approach in zoology we have been led to underrate—as being old-fashioned—the fundamental work of the naturalist in which Tattersall showed such skill. Yet he has left a permanent mark on the literature of his subject, and his name will be honourably remembered when much that is modern has passed into forgetfulness. His many friends will remember him for his genial, good-humoured outlook on life and personal charm, for his intellectual honesty and for the cheerful courage with which he faced adversity. Stanley Kemp.

Mr. J. J. A. Jones

We regret to record the death on November 1 of Mr. John Jenkin Ashton Jones, of the Central Research Department of the United Steel Companies Ltd., Sheffield, and well known in metallurgical research circles.

John Jones was born in 1894, and graduated from Aberystwyth in 1915. Shortly afterwards he joined the Royal Welch Fusiliers and saw active service in the War of 1914–18, during which he was awarded the Military Medal. In 1917 his military service was terminated as the result of wounds, and he joined the Research Department at Woolwich, where he assisted Dr. R. H. Greaves. In conjunction with the latter he presented four papers before the Iron and Steel Institute, of which he became a member in 1920. He was co-author of one other paper, and in his own name contributed six further papers to the Institute.

In 1930 Mr. Jones joined the United Steel Companies Ltd. and, with Dr. T. Swinden, director of research, he took a large part in planning the Central Research Department of that group at Stocksbridge. When the Central Research Department opened he became the manager, a post he held to his death. He leaves a widow and a son and daughter.

Mr. Jones represented the best type of scientific worker, and the quality of his scientific papers needs no elaboration. He did much other valuable work which was not so well known. His quiet yet forceful personality and the multiplicity of his contacts gained him many friends, to whom his many other qualities endeared him. As an example of his modest selfeffacing personality, it may be noted that many who knew him intimately were quite unaware of his distinguished military record. His death will be deeply felt by all who were in contact with him in personal, business and scientific relationships.

WE regret to announce the following deaths:

Dr. Cecil C. Jones, president and chancellor of the University of New Brunswick, where he was professor of mathematics during 1906–31, on August 19, aged seventy-one.

Mr. G. W. Littlehales, hydrographic engineer to the U.S. Hydrographic Office during 1900–32, on August 12, aged eighty-two.

Mr. F. S. Marvin, formerly a staff inspector of the Board of Education, and author of works on the relation of science to civilization, on November 14 aged eighty.

Sir William Noble, a director of the General Electric Co., Ltd., and formerly engineer-in-chief of the General Post Office, on November 10, aged eighty-two

NEWS and VIEWS

A Minister of Reconstruction in Great Britain

THE appointment of Lord Woolton as Minister of Reconstruction with a seat in the War Cabinet follows naturally on Mr. Churchill's declaration in his Mansion House speech on November 9 that it was "a definite part of the duty and responsibility of this National Government to have its plans perfected in a vast and practical scheme to make sure that in the years immediately following the War there will be food, work, and homes for all. . . . No party doctrines or party prejudices or vested interests shall stand in the way of the simple duty of providing before the end of the War for food, work, and homes. They must be prepared now during the War. These plans must be prepared and they must come into action, just like when war breaks out general mobilization is declared. They must come into action as soon as victory is won. On this far-reaching work His Majesty's Government are now concentrating all the energies that can be spared from the actual struggle with the enemy." It may, of course, be inferred that the removal of Lord Woolton from a post which he has filled with such conspicuous success is an indication that Mr. Churchill does not expect the food problem again to become acute. It is equally an indication of the Prime Minister's assent to the principle that preparation for post-war reconstruction has become an urgent necessity and of the importance which he attaches to the Ministry of Reconstruction.

Sir William Jowitt, who as Minister without Portfolio has hitherto been "charged with the duties of reconstruction", will assist Lord Woolton, and the introduction of new blood at the Ministry of Health, which has so much to do with housing, in the person of Mr. H. U. Willink, may be a further indication of the importance now officially attached to reconstruction. The Government's acceptance, in principle, of Lord Balfour's demand last week for early legislation to permit the prompt acquisition of reconstruction areas "at prices related to pre-war values" gave the impression that this obvious and essential measure will soon be made law. The further admission drawn from Lord Snell that "the Government accepts the principle of national planning without qualification", and the Barlow Commission's planning proposals with qualifications, is also reassuring; while in reply to a question from Mr. John Parker on November 10 the Prime Minister denied that the vesting in the State of the rights of development in all land outside built-up areas (proposed by the Uthwatt Committee) was barred as a possible subject of legislation in the present Parliament because of its controversial character.

The precise scope of Lord Woolton's work has not yet been explained. It may be presumed to be administrative rather than the originating of policy, and that Lord Woolton will be principally engaged in supervising and co-ordinating the Government's plans for food, work and homes. Lord Woolton may not have as wide a scope as Lord Addison in 1917 for his task in focusing all the departmental activities, but in sorting out priorities and in seeing that all the necessary legislation is prepared, including laying out the structure of the new social security scheme and forcing concrete decisions on physical planning and in housing, there is ample scope for Lord Woolton's active mind and administrative resource. Whether or not his responsibilities extend to demobilization and to all the policies that are comprised in full employment, it is a great asset to have in charge of reconstruction a man free from Party ties, and the path to agreement on a common programme should be easier.

Centenary of Ferdinand R. Hassler, 1770–1843

ON November 20, 1843, the death occurred of the Swiss-American mathematician and geodesist, Ferdinand Rudolph Hassler, who was the first superintendent of the United States Coast Survey, now the United States Coast and Geodetic Survey. To-day the Survey is responsible for hydrographic, geodetic, tidal, magnetic and seismological work throughout the whole of the United States dominions from Florida to the Aleutians, but when it was founded the United States only fronted the Atlantic seaboard. The suggestion for the Survey came from the American Philosophical Society, the recommendations of which were adopted by President Jefferson, and it was through the Society that Hassler became connected with it when Congress on February 10, 1807, passed the necessary law. Hassler had only been in America two years then, but he had taken with him a library of more than 3,000 volumes and a good collection of instruments, and it was his interest in science which had led to his contact with the members of the Philosophical Society.

Hassler was born in Aarau, Switzerland, on October 7, 1770, and was the son of a well-to-do watchmaker. At the University of Berne he gained a knowledge of mathematics and surveying and afterwards was engaged on a trigonometrical survey of Switzerland He married in 1798, and in 1805, owing to the political unrest of the time, joined a party of emigrants who planned to settle in the southern States. On their arrival in Philadelphia the would-be colonists met with various difficulties, but Hassler's scientific attainments stood him in good stead. Hassler's plans for a coast survey were adopted, and he was appointed to start the work. There was, however, much delay. Having during 1807–9 held a chair of mathematics at West Point Military Academy and during 1809–11 a chair of natural philosophy, in the latter year he was sent by the Treasury to England to purchase instruments. Owing to the War of 1812 between Great Britain and the United States, it was three years before he was able to return to America. The survey was actually started under Hassler's superintendentship in 1816, but two years later he was deprived of his post owing to new regulations which allowed only naval and military officers to be employed. During 1819 he was astronomer to the party sent to settle the north-eastern boundary, but then he was thrown completely on his own resources. For ten years he farmed, somewhat unsuccessfully, in New York State, taught and wrote mathematical text-books. For a time, too, he was employed at the New York Custom House, and then in 1832 when the Survey was reorganized—its work had been practically suspended—he once again became its superintendent. Though sixty-two years of age, he entered upon his work with enthusiasm, assembling the necessary instruments, training assistants and commencing operations in the field. In this work he was engaged until his death at the age of seventy-three at Philadelphia.

Hassler's memory was honoured at the centennial commemoration of the Survey, and in 1929, Prof. Florian Cajori, the historian of science, of the University of California, published his biography under the title "The Chequered Career of Ferdinand Rudolph Hassler". In spite of many troubles—domestic, financial and administrative—Hassler left his mark, and it has been said that "Time has justified the soundness of his ideas", and that "the extension of the survey of the coast to the present day follows his plan, and the field work he carried out more than a century ago is of such high precision that it still forms part of the basic network". As State after State was added to the country, so the work of the Survey extended. Under Hassler's successor, Alexander Bache, the electric telegraph was used in the determination of longitude, and under the third superintendent, Benjamin Peirce, the triangulation was carried from the Atlantic to the Pacific. In the nineteenth century the Survey was responsible for the standard weights and measures; but in 1901 a new department was founded for this work under the title of the United States Bureau of Standards. The centennial celebrations referred to were held in Washington under the presidency of the superintendent, Mr. E. Lester Jones, the President of the United States, Mr. Woodrow Wilson, being among the speakers. A memorial volume was issued, and this contains a portrait of Hassler.

Wellcome Veterinary Research Station

THE Wellcome Foundation has acquired Ely Grange Estate, Frant, Sussex, for the purpose of extending the veterinary research now carried on at the Wellcome Physiological Research Laboratories, Beckenham, Kent. The need for accommodation where experiments can be carried out on farm animals has been felt for some time. The estate will be known as the Wellcome Veterinary Research Station and the resident veterinary surgeon will be Mr. S. L. Hignett, who will be responsible to Dr. R. F. Montgomerie, veterinary research director at the Wellcome Physiological Research Laboratories, where veterinary research, particularly on the laboratory side, will be continued. The full development of the Station at Frant will be delayed until after the War, as the mansion, which will be converted eventually into laboratories, is requisitioned by the Government; but the extensive and modern farm buildings will be occupied and used at once. A start has been made by the acquisition of a herd of pedigree Ayrshire cattle. In addition to the main purpose of the Station, there will be accommodation for the breeding of laboratory animals on a large scale. It is hoped to establish a number of pure lines for this purpose and to do work on genetics in connexion with the breeding of these animals.

Post-War Needs of Universities in Great Britain

SIR JOHN ANDERSON recently stated in answer to a question in the House of Commons that the constitution of the University Grants Committee has been under consideration for some time, and he hopes very shortly to announce the appointment to the committee of a number of new members. As regards the equipment of universities to deal with the post-war situation, the universities themselves have been studying the various problems which will face them after the War. The Committee of Vice-Chancellors and Principals has asked the University Grants Committee to undertake a review of these problems in order to form a considered estimate of the need for increased assistance from the Exchequer. This request will require to be considered as a matter of urgency by the reconstituted Committee; meantime, the universities are being asked to formulate their post-war needs so far as they can be estimated in present circumstances.

Replacement of British Museum's Foreign Books

A GENEROUS offer to replace, so far as possible, the many volumes in the section of non-English books and periodicals which have been destroyed by enemy action in the British Museum has been made by the Allied Governments in London. The offer was put forward by Dr. Philip Argenti, honorary attaché to the Greek Embassy, at a recent meeting of the Books and Periodicals Commission of the Conference of Allied Ministers of Education. Representatives of the Allied Nations pledged their governments to replace, after the War, as a gift, to the best of their abilities, the periodicals and books in their respective languages damaged or destroyed by air attack. The Museum has been invited to submit a list of such periodicals and books to the Commission, classified according to their languages.

The Newcomen Society

THE Newcomen Society met for its annual general meeting on November 10 at the Northampton Institute, London, when the report of the Council for the past year was submitted, and the election of officers took place. The Society has continued to expand, and on September 30 the membership stood at 3,092, irrespective of fifty-five libraries which receive its publications. Owing to the very large increase in membership in North America, the rules of the Society have been amended so that branches overseas can elect their own members and manage their own finances, thus avoiding unnecessary correspondence and expense. The subscription has been raised from £1 to £1 10*s.* for those who elect to receive the *Transactions*. The president for the coming year is Mr. William M. Vermilye, of the National City Bank, New York, who has been treasurer of the American branch for some time. In spite of the difficulties due to the War, a good programme was carried through, and the report contains the titles of seventeen papers and addresses which will ultimately be published in vol. 23 of the *Transactions*. Vol. 21 is in the press and it is hoped will be issued shortly. At the close of the business, special reference was made to the unceasing efforts on behalf of the Society of Dr. H. W. Dickinson. After the business was concluded Mr. R. P. Howgrave-Graham gave a lecture on "Engineering in Early Warfare", the devices of centuries ago being illustrated from documents and pictures.

A New Source of Vitamin C

THE *Biochemical Bulletin*, No. 27, May 1943, published by the Sino-British Co-operation Office, includes among other items of interest an article by T. M. Chen, S. Ho, K. M. Hsieh and T. Shen on "A Very Rich Source of Vitamin C: the Wild Fruit of Emblic from India and S. China". It was thought that this wild fruit might be used as a cheap and convenient source of vitamin C for the Allied Armies in this theatre of war. The tree, *Phyllanthus Emblica* L., bears the fruit, which is "fleshly, depressed, globose, ¾ in.–1 in. diameter, obscurely 6-lobed". The juice is very sour and astringent but contains about ten times as much ascorbic acid by indophenol titration as lemon juice, an average figure of 921 mgm./100 ml. juice being given. This is qualitatively supported by guinea pig tests. It is not toxic for humans, who probably utilize it to the same extent as the crystalline vitamin.

Miners' Welfare National Scholarships

THE trustees of the Miners' Welfare National Scholarship Scheme invite applications for a limited number of university scholarships for award in 1944; there are, in addition, a limited number of exhibitions available for award to the most meritorious of the unsuccessful candidates for scholarships. Candidates must be either workers in or about coal mines in Great Britain, or sons or daughters of such workers, and should not normally be less than seventeen years of age on January 25, 1944. Forms of application and full particulars may be obtained from the Secretary, Miners' Welfare National Scholarship Scheme, Ashley Court, Ashtead, Surrey. Applicants for forms must state whether they apply as workers in or about mines or as children of such workers; those who come within both categories should apply as miners. Applicants already at a university should state, when applying for forms, whether they are first-year students. Application forms must be returned by January 25.

Comet Daimaca

I.A.U. CIRCULAR No. 965 announces that an orbit has been computed for this comet by Mr. Naur from three observations at the Observatory of Bucharest on September 9, 10 and 11. The elements of the orbit are given below.

$$\begin{array}{lll} T & 1943\ \text{Aug.}\ 21{\cdot}538\ \text{U.T.} & \\ \omega & 36^\circ\ 02{\cdot}0' & \rule{0pt}{0pt} \\ \Omega & 82\ \ 15{\cdot}1 & \\ i & 161\ \ 15{\cdot}7 & \\ q & 0{\cdot}75812 & \end{array} \left.\begin{array}{l} \\ \\ \\ \end{array}\right\} 1943{\cdot}0$$

From these elements the following ephemeris has been computed. As the orbit has been derived from short arcs, the figures given below cannot be accepted as very accurate. The comet was stated to be mag. 10 on September 18, when its distances from the earth and sun were 0·32 and 0·92, respectively. As it has receded considerably from the earth and sun since that date, it must be a faint object now, probably about mag. 16.

Ephemeris

Date 1943	R.A. h. m.	Dec.	ρ	r
Nov. 16	18 48·2	11° 56′	2·107	1·658
20	18 51·5	12 25	2·229	1·713
24	18 54·6	12 49	2·342	1·764
28	18 58·0	13 10	2·459	1·823

Announcements

PROF. A. V. Hill, secretary of the Royal Society, is to visit India to advise on problems of scientific and industrial research in relation to reconstruction problems and the co-ordination of such research in India with that elsewhere. His tour is being undertaken at the invitation of the Government of India and with the consent of the Royal Society.

SCIENTIFIC men and many others will learn with much pleasure that Prof. Niels Bohr, of the Institute of Theoretical Physics, Copenhagen, has succeeded in escaping from Denmark and has reached Great Britain.

THE Council of the Royal Meteorological Society has awarded the Symons Gold Medal for 1944 to Dr. C. W. B. Normand, director-general of observatories in India. The medal is awarded biennially for distinguished work in connexion with meteorological science.

SIR GEORGE THOMSON, professor of physics at the Imperial College of Science and Technology, London, has been appointed scientific adviser to the Air Ministry. He will be responsible for examining air operations from the scientific aspect, the methods, weapons and equipment employed, and for advising the Air Staff and other Air Ministry departments on these matters. On all questions affecting radiocommunication and radiolocation Sir George Thomson will work in consultation with Sir Robert Watson-Watt, scientific adviser on telecommunications.

MR. GEORGE HURST has been appointed lecturer in mining and mine surveying in the University of Sheffield. The Rockefeller Foundation has renewed its grant to the University of Sheffield of £400 for research in biochemistry for a further year beginning October 1, 1943.

THE Huxley Memorial Lecture of the Royal Anthropological Institute will be delivered by Prof F. C. Bartlett, professor of experimental psychology in the University of Cambridge, in the rooms of the Royal Society on November 23; he will speak on "Anthropology in Reconstruction".

THE Spanish Cultural Institute at Buenos Aires has recently dedicated a histological laboratory to the memory of Ramon y Cajal; it is under the direction of Prof. Hortegan, one of his pupils.

ERRATUM. In NATURE of November 6, p. 540 col. 2, in the communication signed by Prof. E. F Burton, the size of the fibre used is given as "approximately 0·7 mμ in diameter"; this should be "0·7 μ".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

J. B. Hannay and the Artificial Production of Diamonds

REFERRING to Dr. C. H. Desch's article on this subject in NATURE of August 7, p. 148, I wish to put certain recollections of my own on record.

During the years 1885–96 my father, the late Lord Rayleigh, was one of the secretaries of the Royal Society, and not infrequently mentioned in the family circle incidents which had occurred in connexion with the Society's business, though of course he never gave the names of referees. In particular he spoke a good deal about J. B. Hannay's claim to have produced diamonds, though he never expressed any personal judgment on the matter. It would not have been in his character to do so, without personal investigation.

Hannay sent to the Royal Society a further communication on the artificial production of diamonds at a much later date than that of his published paper on the subject, certainly later than 1890—perhaps about 1894. It may be in the Society's archives, which are at present inaccessible. My father, as secretary, had to deal with it. He made it clear that among the members of the committee of papers (I believe this committee was in fact the same body as the Society's Council) there was distrust of Hannay's good faith. Rayleigh personally found him plausible. Hannay, he said, wrote that the non-publication of his paper seemed to imply disbelief in his good faith, and that as he had offered to demonstrate the matter he thought that this was rather hard. Rayleigh was inclined to agree that it was hard. In Hannay's earlier work, only very occasional success was claimed, and under these conditions a demonstration would scarcely be practicable. I do not know whether at the later period he claimed uniform success. However, the reason why his offer to demonstrate was not accepted was that it was not thought that any demonstration carried out by Hannay could satisfy the sceptics, and no one seems to have undertaken to repeat the work independently.

Hannay wrote a paper "On the Microrheometer" (*Phil. Trans.*, **170**, 275; 1879) which deals with viscosity. This is commented on by R. E. Barnett (*Proc. Roy. Soc.*, **56**, 259–261; 1894), in a paper inspired by T. E. Thorpe, and communicated by him. Barnett gives a very unfavourable analysis of Hannay's work. Since Barnett's paper is not at present easily accessible, owing to libraries having put the volumes of periodicals away for safety, I think some extracts from it may fittingly be quoted.

Hannay gives the rate of flow of various liquids through a capillary tube of stated dimensions. These measurements are not reduced by him to give absolute values of viscosity and thus to admit of easy comparison with the measurement of others, but Barnett points out that all the necessary data are given for such a reduction, which he proceeds to make. He says: "On comparing these results with the values given by Poiseuille Slotte, Sprung, and Thorpe and Rodger as tabulated below (II), it will be seen that Mr. Hannay's observations yield discordant, and indeed, utterly absurd, values for the viscosity of water. At 0°, for example, the viscosity would appear to be below that of any known liquid, and at 6° it becomes *nil*.

"As a matter of fact, it is physically impossible to pass a volume of water such as Mr. Hannay employs under a pressure of 1 m. of water through a capillary of the dimensions given in the time recorded. At 20°, for instance, the time of flow required under these conditions would be about 4600 seconds instead of 131·3 seconds as stated.

"In the light of these results, it would seem to be premature to discuss Mr. Hannay's observations on saline solutions, or to criticise the generalisations he deduces from them."

I have not been able to discover that Hannay made any attempt to reply to this apparently very damaging criticism.

He also wrote a paper on the metallurgy of lead which was read before the Royal Society on April 15, 1893 (see the *Proceedings*), but not published. This paper was, I believe, judged not to have been written in good faith. It is almost certainly still in the Society's archives.

I think that attention should be directed to these facts which, though perhaps not decisive of anything relating to the diamond problem, may nevertheless help in forming a provisional judgment. If Hannay was after all right, they will at least be a contribution to scientific history. The incident about viscosity seems to show clearly enough that his critics had something more than prejudice to go on.

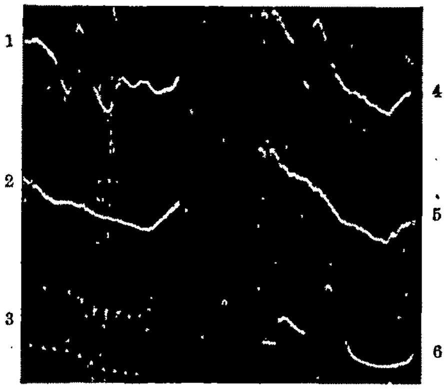
Single-Fibre Response from an Intact Animal

IT is rather difficult to obtain electrical records of the activity of a single nerve fibre, because there are usually present some hundreds of other nerve fibres the contribution of which must be eliminated, and because the shunting of the active fibre by inert tissues or tissue fluid reduces the available action potential to vanishing proportions. It is therefore essential in most cases that the recorded fibre be fairly well isolated both physiologically and electrically, and we are not aware that any records have hitherto been published showing single fibre responses obtained from an animal which has not been dissected nor operated upon in any way.

The median giant fibre in the nerve cord of the common earthworm, *Lumbricus terrestris* L., is especially favourable for such a record, for it may be physiologically isolated from other structures and it has such a large cross-section area that a fair amount of shunting may be tolerated[1].

If a normal lively worm is used the nerve activity is accompanied by muscular action which complicates the record, but if the worm lies in a glass tube just large enough to contain it, it remains quiescent and the record is fairly simple. The nerve is stimulated by a shock applied to the anterior end of the worm, and the record is obtained from leads passing through the glass tube and making contact with the worm's body in the middle region. These leads connect through a balanced amplifier to a cathode ray tube with time base synchronized with the nerve stimulus.

The first record shows the effect of a just threshold stimulus; the least diminution of stimulus gives the



second record. The response therefore exhibits the all-or-none relation to stimulus-strength, it also persists unfatigued by a tetanus of 20 per sec. and is conducted at the same rate as the impulse in the median giant fibre of the nerve cord. This result therefore strongly favours the view that the wave in record (1) is the action potential of the median giant fibre or of structures connected therewith. The grounds upon which we believe that the record does contain the action potential of this fibre itself are these.

The area of cross-section of the median fibre is 0·01 sq. mm., that of the worm filling the glass tube 20 sq. mm. Assuming the mean specific conductivity of the worm to be half that of the giant fibre, the electrical shunting would reduce the recorded wave to 1/1,000 of the nerve membrane potential of 0·1 volt. Hence the recorded wave should be 0·1 mv., which is seen to be of the right order from record (3), which gives a calibration wave of 1,000 cycles at 0·1 mv., peak-to-peak.

The worm is now withdrawn from the tube, opened by a longitudinal incision, and the nerve cord is carefully dissected out and placed in Ringer's fluid. The carcass is replaced in the tube and stimulated as before, but the record shows no wave and is not here reproduced. The carcass is now withdrawn and the nerve cord replaced in it and re-inserted in the tube. The physiological connexions from nerve to worm are now, of course, all destroyed, but the electrical shunting is approximately the same as initially, and records (4) and (5) show the effects of a shock just above and just below threshold, with recording conditions the same as in record (1). The main wave of the first record is repeated, but the subsequent small waves are absent. Finally the carcass was removed, and the nerve cord alone stimulated to give the last record taken at much reduced amplification.

Now this last record is certainly the wave from the median giant fibre, as may be shown by microdissection[2]. Thus the wave in record (4) is clearly the same, but more highly shunted by the carcass. Hence the main wave of record (1) is simply the action potential of the single median giant nerve fibre, and this is followed in the intact animal by other waves with which we are not here concerned.

Osmotic Regulation in *Sabella pavonina*

The Sabellidæ are one of the few families Polychæte worms which have successfully penetrate into fresh water. One of us has previously observe at Loch Ine, Co. Cork, that *Sabella pavonina* Sa occurs in places in which, at low tides, it is subjecte to conditions of low salinity. It seemed of interes to know whether this worm has any power of 'osmoti regulation', and whether the highly developed pa of thoracic nephridia play any part in such regulation. We have carried out some simple experiment on these points.

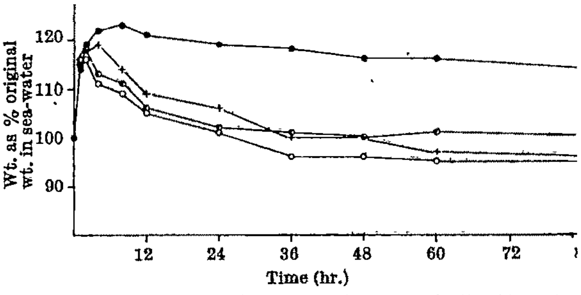
Active regulation in a marine invertebrate may b recognized by following the changes in weight whic result from placing the organism in dilute sea-wate If the animal can regulate, it will retain its origin weight or regain it within a short period. In th following experiments changes in weight of Sabell in different concentrations of sea-water have bee observed.

Preliminary experiments showed that it wa possible to dry Sabella while still in its tube an obtain consistent weighings in a series of drying It was also shown that the weight of the tube di not alter significantly in twenty-four hours on bein moved from sea-water to tap-water. All experiment were consequently carried out with the worms stil in their tubes after these had been trimmed and an attached growths removed. The water in which th worms were kept was changed every twelve hours The temperature varied between 15·2° and 17·6° C

To study the capacity of the worms to regulate the change in weight of individual worms in norma 80, 60 and 40 per cent sea-water was followed fo thirty-six hours. In 80 per cent sea-water the worm regained their original weight within twenty-fou hours; in 60 per cent sea-water the worms rapidl deteriorated in condition, shed their crowns and di not return to their original weight; in 40 per cen sea-water the worms died within twenty-four hour It may therefore be concluded that Sabella has onl limited powers of regulation when transferred suddenly to diluted sea-water.

In order to see whether the thoracic nephridia ar important in regulation, the effect of removing th segments containing these nephridia was studied. A this operation also involves removing the crown, th effect of the absence of this organ was also examined.

Four groups of three worms each were used (*a*) normal worms; (*b*) worms whose crown had bee cut off; (*c*) worms whose crown, thorax and firs three abdominal segments had been cut off to remov the whole of the thoracic nephridia; (*d*) worms fro which about fifteen of the posterior segments ha



●, worms without thorax; ×, worms without crowns; ○, worms without tail segments; ◐, normal worms.

been removed; these were to act as a control against possible effects due to cutting the worms.

These various amputations were performed about sixty hours before the beginning of the experiments, and the worms were kept in running sea-water until required. All experiments were carried out in 75 per cent sea-water. The worms in each group gave consistent results.

The variation in weight of these groups of worms with time is shown in the accompanying figure. It will be seen that while normal worms, those lacking their crowns and those lacking the posterior end all regain their original weight within 36 hours, the worms lacking the thorax show relatively little recovery within 84 hours. It therefore appears probable that the large thoracic nephridia play an important part in the 'osmotic regulation' of *S. pavonina.*

Our thanks are due to the director and staff of the Marine Biological Station at Plymouth for their hospitality to us while carrying out these experiments.

Siderocytes in Mammalian Blood

FOLLOWING the work of Grüneberg[1], I decided to investigate the possibility that the siderocyte might be a degenerating cell, and that the iron might be catabolic in nature. Investigations in stored blood yielded the following results and conclusions.

Siderocytes appear in large numbers in stored blood of cats, dogs and human beings. Apparently all the cells go through a phase as a siderocyte, and it is possible to demonstrate that the siderotic granules are extruded from the red cell. Concomitantly there is a fall in total blood pigment of between 2 and 7 per cent and a corresponding increase in non-hæmoglobin plasma iron and a bilirubin-like substance. The change is affected by the availability of oxygen, inhibited by storage at low temperature, and accelerated by heat and chemical agents. Phenylhydrazine is one of these agents. The change can be effected once only, and after the granules have been extruded the erythrocyte becomes susceptible to phagocytosis.

Carbon monoxide produces a partial inhibition, but the presence of leucocytes does not influence the production of the siderotic material. Fragility changes also occur, and resistant cells resembling "target cells" (Barrett[2]) appear after the extrusion phenomenon.

It is concluded that the siderocyte is not essentially a young cell; that it is probably the stage before the cell is removed from the circulation; that it probably appears in the blood of all mammals; that the iron is catabolic, and that it is closely related to, if not identical with, the 'easily-split' blood iron studied by Legge and Lemberg[3].

A detailed account of the work will be published elsewhere.

Fragility of Erythrocytes in Hypotonic Saline

AN interesting point in connexion with hæmolysis is the variation in the resistance of erythrocytes obtained from the different species of animals towards a particular hæmolysin. It was Rywosch[1] who first attempted a sort of generalization in this connexion by pointing out that the series obtained by writing down the names of common laboratory animals according to the order of resistance of their erythrocytes to hypotonic saline is just the reverse of that obtained by ranging them according to their resistance to saponin hæmolysis. Various suggestions were put forward from time to time to explain this inverse relation, which suggested the possibility of the existence of some factor within the corpuscles which operated in a reverse manner with respect to the lysins concerned.

Subsequent work on the subject, however, showed that Rywosch's contention is neither strictly true for all hæmolysins[2], nor is it applicable to all species of erythrocytes[3]. While working on the fragility of the erythrocytes obtained from some common laboratory animals, in hypotonic saline, it struck us that some erythrocytes known to be of very small size, such as those of sheep and goat, were very fragile, while others of bigger size, such as those of man, dog, etc., were far more resistant.

A closer examination of our data showed that the fragility of the erythrocytes of the species of animals studied, namely, guinea pig, human being, monkey, dog, rabbit, buffalo, ox, cat, sheep and goat varied inversely as their respective average diameter. It remains to be seen whether this relation is a general one and true for all species of erythrocytes.

Determination of Ascorbic Acid in the Presence of Sulphur Dioxide

WHEN an equal volume of 3 per cent hydrogen peroxide is added to a slightly acidified ascorbic acid solution, no appreciable effect on the indophenol titration value is observed, unless iron or copper salts are present. The end-point is a permanent pink colour deepening very slowly on standing. With sulphited fruit and vegetable extracts the sulphur dioxide is converted into sulphuric acid, and the true ascorbic acid value is rapidly obtained on titration. When lesser quantities of peroxide are used, the titration values are slightly lower, and the pink colour deepens more rapidly. Apparently, re-oxidation of reduced indophenol takes place during the titration, along with reduction of the reformed indophenol by ascorbic acid still present. When 1·5 per cent peroxide is present in solution, this effect is negligible. The method has been used successfully for the last three years.

Full details of these observations will be published elsewhere.

Constitution of Calycanine

SOME time ago, on the suggestion of Prof. A. R. Todd, calycanine was examined by X-ray methods[1,2] in order to decide whether a constitution originally suggested by Barger, Madinaveitia and Streuli[3] for a molecule $C_{16}H_{10}N_2$ is in harmony with the crystallographic symmetry and the unit cell dimensions. That investigation established the approximate dimensions of a monoclinic unit cell as $a = 13 \cdot 7$ A., $b = 4 \cdot 45$ A., $c = 9 \cdot 7$ A., $\beta = 107°$, and showed that the space group is $P2_{1/a} - C^5_{2h}$, provided that a few very weak reflexions are neglected. If these reflexions are taken into account, it was suggested that the above cell should be regarded as a pseudo-cell, the true unit cell having a doubled c-axis, $2 \times 9 \cdot 7$ A. Fairly detailed suggestions were advanced as to the probable crystal structure, but the chemical synthesis which Prof. A. R. Todd intended to carry out has not been completed because of the War.

Recently, Prof. Todd pointed out to us that a totally different molecule $C_{21}H_{15}N_3$ has been proposed by Manske and Marion[4], and suggested that our X-ray data might enable us to decide unequivocally whether this new molecule can be regarded as a possible alternative to the molecule $C_{16}H_{10}N_2$. We have therefore re-examined our original X-ray data, and have supplemented it with new photographs from different crystalline specimens, with the following results.

The dimensions of the monoclinic (pseudo) cell have been determined more accurately as $a = 13 \cdot 7$ A., $b = 4 \cdot 45$ A., $c = 9 \cdot 8$ A., $\beta = 110 \cdot 5°$. The density of calycanine is $1 \cdot 34$ gm./c.c., so that the mass of this unit cell is 750×10^{-24} gm. The masses of molecules $C_{16}H_{10}N_2$ and $C_{21}H_{15}N_3$ are 379×10^{-24} gm. and 510×10^{-24} gm., so that this cell would contain $\frac{750}{379}$ or $\frac{750}{510}$ molecules, that is, $1 \cdot 98$ or $1 \cdot 47$ molecules, according as one formula or the other is selected. Thus within the accuracy of our measurements this cell may contain either two molecules $C_{16}H_{10}N_2$ or $1\frac{1}{2}$ molecules $C_{21}H_{15}N_3$. If this is the true unit cell, the second alternative can be rejected, since a unit cell cannot accommodate a fractional number of molecules.

In general, an approximate determination of the cell dimensions and density would suffice to decide between alternative molecular formulæ ; in this case, however, it happens that a cell with doubled c-axis (as suggested in our original examination of calycanine[1,2]) would contain a whole number of molecules (four or three) for either of the molecules proposed. It therefore becomes necessary to consider very carefully the significance to be attached to the additional weak reflexions which originally led us to propose a true unit cell with doubled c-axis.

Our new photographs again show additional weak reflexions, but, partly because of the shape of these diffraction spots, partly because of their positions in the oscillation photographs, and partly because of the difficulty we have found in systematizing their appearance in photographs from different crystalline specimens, we now incline strongly to the view that they arise from one or more differently oriented crystalline fragments attached to, or grown as part of, the main crystal exposed to the X-ray beam. Because of the peculiar optical properties of calycanine[1], such crystalline fragments are not detected by the usual microscopic examination. The possibility of a true unit cell with doubled c-axis is not definitely excluded; but we do not now consider that there is any very definite evidence for its existence, and if the *true* unit cell has $c = 9 \cdot 8$ A., then the formula $C_{21}H_{15}N_3$, suggested by Manske and Marion, is apparently excluded, while the formula $C_{16}H_{10}N_2$ suggested by Barger, Madinaveitia and Streuli and by Prof. Todd is acceptable. The detailed discussion[1,2] of the probable crystal structure is unchanged in essentials, though slightly modified in detail, if the small cell ($c = 9 \cdot 8$ A.) is the true unit cell.

If, however, we still take the cautious view that the true cell may have the doubled c-axis, it is still necessary to consider under what conditions three molecules ($C_{21}H_{15}N_3$) could be accommodated in it. It appears that this would necessitate the selection of *either* a triclinic space-group *or* a monoclinic space-group without $\{h0l\}$ halvings, so that in either case well-established features of the crystal symmetr must be left out of account. No such difficulties arise, of course, in placing four molecules ($C_{16}H_{10}N_2$) in the larger cell.

We may summarize by saying that all the evidence, whether direct or circumstantial, is satisfactoril explained if the molecule is $C_{16}H_{10}N_2$; but that a molecule $C_{21}H_{15}N_3$ can only be brought into harmon with observation by the adoption of a series of unusua and unlikely suppositions which still leave unexplained certain prominent features of the experimental data.

Non-Solar Planetary Systems

OBSERVATION has revealed the existence of at leas two planetary systems attached to binary stars ver near our solar system[1]; and the suggestion that ther are numerous planetary systems in the universe gain ground. It is interesting to examine the differen conflicting theories of the origin of the solar systen in the light of these observations.

On the tidal theory of Jeans and of Jeffreys planetary systems originate only at the rate of abou one per 5,000 million years. Taking the generall accepted short time-scale for the age of the univers —an interval between 10^9 and 10^{10} years—we fin that there can be at most two planetary systems i the galactic system, on Jeans's theory. The probability of collisions is still less on Lyttleton's binar star collision theory[2], and there is scarcely an chance for the formation of a planetary system.

On Banerji's Cepheid theory[3], in which the sola system is supposed to originate from the oscillator instability of a Cepheid due to the gravitationa attraction of a passing star, the probability of formation is very much greater, as a grazing or even clos encounter is not necessary in this theory. In fact Banerji concludes his theory with the following words "One conclusion seems to be irresistible. If the theor be correct in its essentials, there may be more planet ry systems than at present supposed". The recent observations support Banerji's conclusion.

The detection of planetary systems in binary stars also lends support to the Cepheid theory of the origin of binary stars recently advanced by me[4]. Owing to radiation of energy and consequent increase of angular velocity, a Cepheid was supposed to break up into a double-star system. There is a chance of planets being formed from the filament connecting the two stars.

Propagation of Potatoes

DR. L. G. G. WARNE[1] is to be thanked for pointing out Loudon's writings on this subject. The works of J. C. Loudon (not Louden) indeed contain references to emergency methods of potato propagation which recent authors in several countries had thought to be new, even if these authors recognized approximaions to some of these methods among the practices of their more economical forefathers. Thus already in the first edition of "An Encyclopedia of Gardening", the date on the title page of which is given as 822, there appear in one form or another all the notes and quotations given by Dr. Warne[1] from the 871 edition, while again in the first edition of "An Encyclopedia of Agriculture" (1825) Loudon mentions among means of propagation having strenuous support in some quarters "on the ground of experience . . . small cuttings, sprouts, shoots, or even nly the eyes or buds".

Three points call for further comment:

(1) Following a later edition of "An Encyclopedia of Gardening", Dr. Warne writes, "the sprouts generlly found on store potatoes in spring may, when carefully planted in loose well-prepared soil, be made o yield a crop"—whereas the corresponding remarks in Loudon's first edition read, "the sprouts which are generally found on store-potatoes in spring, and picked off and thrown away as useless, *will*, when carefully planted in loose well-prepared soil, *yield a crop*; and this crop will be fit for use a little sooner than one produced from cuttings or sections of the same tubers" (the italics are mine). In this connexion it may be added that my own tests with detached sprouts[2] have been successful again this year.

(2) Dr. Warne further quotes from Loudon, "In making the sets or sections reject the extremes or watery end of the tuber" (extreme is in the singular in both the 1822 and 1850 editions of "An Encyclopedia of Gardening"). This is the antithesis of the basis of the widely publicized Russian method which exressly advocates use of the rose or 'top' end as eing the most active part of a large tuber. However, after the removal of this end and, with it, of the dominant sprouts which are also the most active in the production of growth-retarding substance[3], sturdy productive shoots may be obtained also from the 'heel' (proximal) end of the tuber as well as from the lateral eyes.

(3) Scientific literature, however old, can scarcely e dismissed as 'dead' unless it is wholly superseded r proved to be ill-founded. Nowadays, with the rapid strides and great expansion of the plant sciences, it has become practically impossible for even the most active exponent to 'keep up' in more than an ever-narrowing field of specialization; yet many workers have, of necessity or because they feel it to be their duty, from time to time to go outside their own immediate field. All the more easy, then, to miss pertinent references and repeat the work of others unnecessarily.

International Languages

RECENT references to international languages in NATURE bring home the necessity of a more thorough inquiry into their possibilities, and into the causes that have so far precluded their wide use. There can now be no doubt that artificial international languages have been constructed that can be learnt in a very small fraction of the time required by any natural language. In spite of this, their anticipated use in international communication has not become general.

A common reason given for their adoption is that they can serve as a tool for international organizations. It is here that the barrier to their use is apparent, since for the last generation international organization generally has been under a cloud.

If after the War we put aside the national rivalry of the last interbellum, its place will need to be taken by international organizations of a robuster nature than hitherto, including both organs of government and cultural international societies. These, if they are based on continuous popular activity, will need a language for their use. (It is less certain that specialized international vocations, such as trade in defined channels, will create a demand for an international language, and the same probably applies to occasional conferences and to the study of foreign countries in detail.) Which international language is to be used must depend on the users. The language for a European or American-European federation might well consist of roots from European languages. A union centred on the English-speaking peoples might well use one based on English. It is conceivable that several might be in use simultaneously in the parliaments of different federations or by different cultural organizations. In view of the ease with which they are learnt, even this would be a gain on the present position, while it would also provide an experimental basis for future work on international languages.

But if one international language is to receive enduring and universal recognition, we require a stable international political and cultural balance, and to know something of the relative importance of the different national cultures therein. How far is this about to be realized? At present we can make some estimate of the future importance of some of the protagonists of this War. Only to a less extent can we foretell the importance of the countries of Asia, South America and Africa. Is it possible to make a reasonably good forecast, to get it accepted, and so to decide the type of international language likely to secure lasting adoption?

E. T. HARRIS.

"Hazelwood", Ivy Road,
Bolton, Lancs.

James Prescott Joule and the Unit of Energy

ALTHOUGH it appears from earlier letters[1] that no definite agreement can be reached about the pronunciation of 'Joule', the following points may be of interest concerning a possible origin of the name and of its different pronunciations. According to A. Schuster and A. E. Shipley[2]: "Joule's name appears to be derived from 'Youlgrave', a village in Derbyshire where his family originally resided". It would, perhaps, be more correct to say that both 'Joule' and 'Youlgrave' had a common origin, the former in the English or Scandinavian personal name 'Iola', the place-name then meaning 'Iola's grove'. A. Mawer and F. M. Stenton[3] give this meaning, though E. Ekwall[4] suggests instead, 'yellow grove'.

Various early forms of the place-name have been noted; for example, 'Yolegrave' (1259) and 'Jolgreve' (fourteenth century), and there are many more recent forms. Indeed, the Rev. P. Hadfield, vicar of Youlgreave, has kindly informed me that he believes there are about forty different spellings to be found in the registers and old churchwardens' accounts, a few examples being 'Yolgreave', 'Yolegrave', 'Yoolgrave' and 'Yoolegrave'. These forms seem to indicate variations in pronunciation. At present 'Youlgreave' is pronounced as in 'pool' and 'grave', though the inhabitants who speak the dialect pronounce it 'Yolgrav', as in 'doll' and 'have'—this on the authority of Mr. Hadfield. He states, further, that between 1750 and 1790, the name 'Joule' is found frequently in the registers always with that spelling. He does not say whether he has carried his investigations back to an earlier date. The Joule family had a mill at Alport in Youlgreave parish, and about twelve years ago a person named Joule visited Youlgreave; he claimed to be a descendant of the original family and was writing a book thereon.

Finally, Mr. Hadfield gives the pronunciation of the personal name as 'Jole', but himself thinks there is no direct connexion between the names 'Joule' and 'Youlgreave'.

[4] Ekwall, E., "The Concise Oxford Dictionary of English Place-Names" (1936).

IF the desire is to pronounce the name as it was pronounced by the family and by the friends of Dr. Joule, there can be no doubt it is 'Joole', so as to rhyme with cool, tool or rule. Professors of the University of Manchester, in the 'eighties of last century, such as (Sir) Henry Roscoe, Balfour Stewart, (Sir) Arthur Schuster and Osborne Reynolds, all friends and some close friends of Dr. Joule, all pronounced his name in this way. Forty years ago, when as chairman of a committee for erecting a memorial to Dr. Joule in Sale Park, I met his son, Mr. B. A. Joule, he told me 'Joole' was the right pronunciation, and that in old family deeds the name was written 'Youle', like the name of the village Youlgreave in Derbyshire in which the family lived It would be interesting if the upholders of the pronunciation 'Jowl' would cite their authorities.

It may be worth recording the opinions of Mr Joule as to the published photographs of his father The beardless face at forty-five years of age in th engraving in the memoir by Prof. Reynolds h thought too long, while the bearded face publishe by NATURE and reproduced in vol. I of Joule' "Scientific Papers" he thought good. A still late photograph by Lady Roscoe, said by Reynolds to b "particularly good", is reproduced in Sir Henry Roscoe's "Life and Experiences" (Macmillan, 1906)

C. H. LEES.

Greenacres,
Tonbridge.
Nov. 3.

THE workers in physics and engineering, respectively, in the University of Edinburgh, who wer contemporary with Joule, were Tait and Fleemin Jenkin. Tait was a perfervid supporter of correc pronunciation of proper names: witness his jok regarding his fellow pupil at the Edinburgh Academy Tate, afterwards archbishop, as a man who did no know how to spell his own name.

In the course of a prized twenty-year fellowshi with Tait, wherein Joule and his work were referre to with at least annual frequency, the pronunciatio I heard Tait use was invariably that which rhyme with 'pool' or 'cool'. There can be no doubt that thi was Joule's own, I feel sure.

The testimony of relatives of Fleeming Jenki would be of much value.

"Timbers of the New World"

IN his review of Record and Hess's "Timbers the New World"[1] Mr. Alexander L. Howard devot half of a long paragraph to a mild reproof of t authors for saying something which actually the never said. He writes: "The authors state '*Swieten* [is] the source of the only and true mahogany', whic pronouncement may be correct, and also may not' The text (p. 366) reads: "*Swietenia,* the source the original or true mahogany".

There is enough evidence produced (p. 369) th the name mahogany was originally (1671) and st is applied to a tree which since 1760 has been know to science as *Swietenia*. The expression "original true" was meant to convey the meaning that "tru mahogany is the kind to which the name mahoga was first applied, just as the orginal or true cedar *Cedrus*. Thus it is only through misquotation that mere statement of fact opens "a very controversi subject". The senior author has publicly express his opinion on this subject, but not in "Timbers the New World".

THE NEW ALGEBRAS

PROF. E. T. WHITTAKER'S presidential address to the Royal Society of Edinburgh, delivered on October 25, on "The New Algebras and their Significance for Physics and Philosophy", contains a characteristically lucid account of the main features of non-commutative algebra and its application to modern physics. Its significance for philosophy follows perhaps by implication; but it is to be regretted that, presumably through limitation of space, this interesting aspect of the subject received no specific treatment.

It is appropriate that the occasion of the address hould fall almost exactly a hundred years after the discovery of quaternions by Hamilton, for this event, as Prof. Whittaker points out, marked the beginning of the emancipation of algebra from the confines of classical ideas, according to which algebraic symbols necessarily obeyed the rules of numbers. Quaternions were devised to represent *operations* (actually operaions of spatial rotation, but the general principle involved is capable of much wider application), and he order of performance of two operations, unlike the order of multiplication by two numbers, has in general an effect on the result obtained. In the developments of the new idea, such as Boolean algebra, Pierce's logic of relatives, Whitehead and Russell's logic, and Cayley's matrix algebra, the symbolism traditionally employed for elementary processes with numbers is adopted for different, though somewhat analogous, processes with operators, so that, for example, abC, which in classical algebra stands for the product of a, b and C and is identical with baC, stands in operational algebra for the operation b performed on C and the operation a on the result. It is not, in this case, normally equivalent to baC.

Prof. Whittaker gives some interesting examples of this generalization of symbolic processes, and then introduces the conceptions of modern physics in which scope has been found for its application. The older physics sought to interpret physical events in terms of moving mass-points, and for this interpretation the algebra of numbers was adequate. The refined experiments now possible, however, show that such an interpretation is not admissible for the extremely small entities with which modern physics is concerned. We can no longer think of those entities as particles. "We have no right to postulate the existence of entities which lie beyond the knowledge actually obtainable by observation, and which have no part in the prediction of future effects. Thus the classical concept of a particle must be discarded; in its stead there has been introduced a new fundamental element in the description of the external world, which is called a *state*". States are "events which extend over more than one point of space and more than one instant of time and which yet are *ultimate* events; that is, they cannot be analysed into anything simpler than themselves".

For the representation of states, numbers are inappropriate. The position and momentum of an ultimate physical entity can no longer be regarded as separate quantities, each specifiable by its intrinsic numerical measure. They have to be taken together and represented by a joint symbol, and the problem s to find symbols the rules of manipulation of which it them to represent the physical situations which actually occur. It turns out that a new algebra of the type introduced by Hamilton, in which 'multiplication' is not commutative, meets the case; it is the matrix algebra of Cayley. This algebra "is, in fact, the symbolism appropriate to things that cannot be measured exactly", although, of course, all observable results obtained by its use must agree with the facts of observation.

Prof. Whittaker gives an example to show how the idea of an operator may be regarded as an extension of the idea of an ordinary number, thus justifying the use of the word 'multiplication' for what are essentially two different processes. In this connexion an illustration occurring in Kelland and Tait's "Introduction to Quaternions" is worth recalling. (Incidentally, Prof. Whittaker speaks appreciatively of Tait's efforts to make known the importance of quaternions.) The extension of the idea of multiplication from whole numbers to fractions involved a generalization as difficult to understand in its day as the extension to operations now is. Originally, multiplication implied a process of addition; to multiply by 3 was to add three numbers together. 'Multiplication' by $\frac{1}{2}$, however, is in no sense an addition, and the result is, in fact, to give a smaller number. This is, in essence, as paradoxical as the non-commutability of matrix multiplication.

N.Z. DEPARTMENT OF SCIENTIFIC RESEARCH

THE seventeenth annual report of the Department of Scientific and Industrial Research, New Zealand, covering the year 1941–42, includes the Minister's statement, the secretary's report, and reports of the various research committees of the Council, on research work at the agricultural colleges, on the work of the Dominion Laboratory, the Dominion Observatory, the Dominion Physical Laboratory, and the Geological Survey, as well as of the Magnetic Observatory, Christchurch.

The Department's activities have continued to be concentrated on problems arising out of the War, but both the Dominion Physical Laboratory and the Radio Development Laboratory have been established in improved buildings and provided with additional skilled staff to give greater assistance to the three Fighting Services and the munitions industry. Important defence scientific units have been established at the University of Otago, and at Auckland and at Canterbury University Colleges. The first commercial dehydration plants for butter, vegetables and meat came into operation during the year, and the plants are giving very satisfactory dried foodstuffs, largely because of the scientific effort put into their design and to previous testing on pilot plants by the staff of the Department. Investigations have been extended to examination of the raw materials used, their pre-treatment to conserve their food values and vitamin contents, and to their packaging in a form suitable to retain high quality when used as army rations by troops operating in difficult field conditions. Work on an up-to-date fruit dehydrating plant is well advanced.

Maps showing the soil types occurring in the North Island have been completed, and, based on these maps, others showing soils which will respond to lime treatment in different degrees have been prepared. A map of the areas suffering from erosion in the mountainous region of the South Island has been completed, and soil surveys have been made of three of the important linen flax districts of Otago. During the year a Building Research Committee was established by the Department which is giving consideration to the numerous problems which will arise and require investigation in connexion with materials necessary for the construction of houses after the War. The Department's activities have been closely associated with similar activities in Great Britain, in other Dominions, and in the United States of America.

The report of the Dairy Research Institute refers to continued work on problems designed to reduce the damage done through bacteriophage entry into both single strain and mixed strain starters used in cheese factories, as well as on the control of cheese mites, for which purpose ethyl bromide proved a satisfactory fumigant without detriment to the flavour of the treated cheese. Dried butter fat has also been produced. Under the Food Cold Storage Research Committee, work has continued on the refrigerated gas storage of apples, the effect of fertilizers on cold-storage quality, and on the orchard storage of apples. Other work under the Fruit Research Advisory Committee included long-term manurial investigations on apples, minor element studies and further successful trials with modifications of the normal spray programmes.

The Leather Research Association has commenced an investigation on the flexibility of sole leather. The Shoe Research Association has also been concerned with investigations on adhesives. The Cawthron Institute has continued investigations on the mineral content of pastures, while among the activities of the Mineral Resources Committee may be mentioned those on refractories and oil shale, and the preparation for publication of a full report on the geological survey of Chatham Island peat deposits and the chemical investigation of the wax. The Wool Manufacturers' Research Association has given much time to the introduction of the wet chlorine process of producing unshrinkable woollen garments, and to the examination of new unshrinkable processes, as well as to the influence of hairiness on processing.

Under the Plant Research Bureau the Agronomy Division has continued its investigations on linen flax, including the mite infestation of flax seed in store, for which purpose a dressing of 'Ceresan' has given good protection. The Botany Division, Wellington, has continued work on seaweed utilization, medicinal plants, rubber plants, and fibre plants. Good progress has been made during the year in the establishment of hard-wearing turfs for aerodromes, while the Plant Diseases Division has continued its work on vegetable diseases and pests, particularly the control of the carrot rust fly, late blight of tomatoes, and downy mildew of onions. Under the Timber Protection Research Committee the State Advances Corporation has continued field investigations of timber-infesting insects and fungi, the field application of termite control and the field application of wood-preservatives.

The report also includes a summary of the more important results emerging from the 1942–43 season's work of the Tobacco Research Advisory Committee. Entomological investigations at the Canterbury Agricultural College have included sheep-dipping experiments and work on insect pests of wheat and of cocksfoot. Animal production research has included studies of the nutritive value of New Zealand mutton and lamb, and the preparation of hormones. Work at the Wool Metrological Laboratory has been considerably curtailed, but the analysis of survey data collected during 1941–42 has been continued. The Massey Agricultural College has continued its experiments on sheep nutrition, drainage research, root development studies, and on sheep-breeding methods, as well as on pig research.

The report of the Dominion Physical Laboratory refers to investigations on pyrometric control, the chromium plating of gauges and tools, surface metallizing of mirrors, high-speed cross-bearings, measurement of low illumination, repair of lightning arresters, mould on wallboard, and on physical problems in the linen flax industry.

RESEARCHES ON PENICILLIN

So much has been written about penicillin, the bacteriostatic substance extracted from *Penicillium notatum*, that one hesitates to add more at a time when its properties, which are so remarkable that they seem to be almost magical, are still being investigated in Great Britain and elsewhere. It is clear that everything possible is being done to make this beneficent substance available in quantities as large as possible and to investigate to the full its possibilities.

E. Chain, H. W. Florey, M. A. Jennings and T. I Williams (*Brit. J. Exp. Path.*, 24, 108 ; 1943), working in Oxford, where already so much pioneer work on penicillin has been done, have continued the work of W. H. Wilkins and G. C. M. Harris (*Brit. J. Exp Path.*, 23, 166 ; 1943) and report the isolation in a crystalline state of helvolic acid, which, like penicillin is especially active against Gram-positive organisms and is chiefly bacteriostatic rather than bactericidal It is soluble in most organic solvents, but is insoluble in water, although its sodium salt is readily water soluble. Leucocytes are not affected by dilutions of it of more than 1 : 1,600 and tissue cultures can be exposed to dilutions of 1 : 2,500 for forty-eight hours It is excreted in the urine and bile. A high antibacterial titre can be maintained in the blood, but repeated injections of it damage the liver.

Another worker is briefly noted in the *Journal of the American Veterinary Medical Association* (102 385 ; 1943). The only reference given to the source of this note is that it is abstracted from *Science Digest* of an unstated date. The reference is to a substance which has been called 'penatin', discovered by W Kocholaty at the University of Pennsylvania. It is claimed that penatin has an even higher 'microbicidal power than penicillin (penicillin does not kill bacteria it inhibits their multiplication) and a wider range of application. It is claimed that "50 pathogenic and non-pathogenic species yielded to its action in dilutions as high as 1 : 400,000,000". Anthrax, diphtheria, typhoid, paratyphoid, brucellosis, pneumonia and pus-forming micro-organisms were 'killed' with dilutions of 1 : 12,500,000. Its action was not lowered in 90 per cent serum, and rabbits and guinea pigs suffered no obvious ill-effects from "large intravenous injections".

Readers who wish for further references to the properties of penicillin will find useful the article by M. E. Florey and H. W. Florey (*Lancet*, 387 ; March 27, 1943) on its general and local administration and the leading article in the *Lancet* (106 ; July 24, 1943 entitled "Penicillin in America". The latter article gives further references. J. Mackintosh and F. R

Selbie (*Lancet*, 793 ; June 26, 1943) compare the action of penicillin with that of some of the sulphonamides and compounds of the flavine type on anærobic infections of wounds, and a leading article in the *Lancet* (781 ; June 19, 1943) discusses the evaluation of wound antiseptics, with further reference to the literature of this subject. Sir Henry Dale, in his Frederick Price Lecture (*Brit. Med. J.*, 411 ; Oct. 2, 1943), briefly deals with penicillin and with the training, by cultural restriction, of a soil bacillus to produce gramicidin, which acts chiefly on Gram-positive cocci. It is clear that the Gram-positive organisms especially, and a good many others as well, are in for a pretty bad time in the years ahead.

Since this note was written the following important further articles on penicillin have appeared : "Progress with Penicillin" (*Lancet*, 546 ; Oct. 30, 1943) ; "Penicillin in the U.S.A." (*Brit. Med. J.*, 582 ; Nov. 6, 1943), both of which deal with American work, and the interesting paper by G. J. Harper (*Lancet*, 569 ; Nov. 6, 1943) on the destruction of penicillin by the penicillinase produced by certain bacteria.

WOOD UTILIZATION

THE Utilisation Branch of the Forest Research Institute at Dehra Dun, India, continues its issue of practical war research investigations in the Bulletin and Leaflet series of the Institution's publications. *Ind. For. Bulletin* No. 118 (For. Res. Inst., Dehra Dun, published 1943) discusses "Studies in Fire Resistance" of some Indian timbers. Experiments have been carried out on the rate of burning of fifty-two species of Indian timbers, and the influence of various factors like the structure of the wood, physical properties and so forth on the natural fire-resistance of wood is discussed by the writers of the bulletin, D. Narayanamurti and R. Gopalachari. In the present time when the public have come to regard iron and concrete as the chief materials in building construction, it may cause surprise to read the following recorded opinion of the investigators. It merits consideration and further investigation, when in Great Britain there is so much rebuilding and new building to be undertaken.

Wood, despite its many favourable properties, is held by many to be less valuable than iron or concrete because of its inflammability. Combustibility is not always the only criterion to be considered in a material of construction, and even when it is important careful investigation shows that wood behaves better than the other materials when exposed to fierce fires. Natural stones burst even on slight warming, and iron even at 500° C. loses half its strength. The loss of elasticity in heated iron leads to changes of form and shape so that sudden collapse without warning is unavoidable. With wood, in the early stages of fire, any small loss of strength due to the surface burning is compensated for by a loss in moisture content which increases its strength. Another defect of iron is its high thermal conductivity, which is more than two hundred times that of wood. For fire-fighting services also a wooden structure is less dangerous, and the clearing up of wooden wreckage is also easy. By proper methods of construction and suitable chemical treatment wood can be made very fire-resistant. The bulletin is written mainly for India; but the position of wood *vis-à-vis* iron and concrete is well worth a close consideration in the great building schemes facing Britain.

In *Ind. For. Leaflet* No. 42 (Res. Inst. Press, 1943) on "Preliminary Studies on Improved Wood", by D. Narayanamurti and Kartar Singh, the importance of wood from time immemorial for construction and fabrication is noted. 'Availability' and 'low cost' are two of the reasons given. In some parts of the world, however, neither of these statements is correct, notably in Britain. The leaflet discusses the results of experiments to improve the properties, in other words the resistance, of wood by impregnation with synthetic resins and other materials. Impregnation with resins is found to increase the density and compressive strength. Under suitable conditions it is possible to increase the compressive strength per unit specific gravity considerably—but attention is directed to the limitations of the process.

An *Indian Forest Leaflet* (No. 37 ; 1943), "How to Identify Timbers", Part 3, is a continuation of this subject. The author, K. A. Chowdhury, states that Part 1 of the series should be read in conjunction with the present one. The importance of the investigations dealt with in Part 3 lies in the fact that the timbers investigated in the Wood Technology Section have been those thought to be most suitable for motor-lorry bodies. It is well known that in the provision of equipment for the great armies in India that country has become inevitably more and more self-supporting. The leaflet gives a key for the field identification of important Indian timbers used for motor-lorry bodies. Short anatomical descriptions of these timbers have also been included. The importance of this type of information available to the local forest officer in the field is scarcely realizable to the layman. But anyone who has examined a great raft of logs consisting of the whole boles of the trees after floating down several hundred miles of a tropical river, with the object of identifying the botanical species of the logs, will have little difficulty in appraising the importance of this type of research.

PHYSIOLOGICAL BASIS OF CAMOUFLAGE

THE methods of camouflage and of reconnaissance in modern warfare are, to a great extent, conditioned, and even limited, by the potentialities of our visual and acoustic perceptions. Military experts are little acquainted with the scientific side of the problem of human senses and perceptions, while physiologists and psychologists have not yet paid sufficient attention to the application of their knowledge to the evaluation of the 'human factor' in war.

The recently created laboratory for the study of perceptions at the Institute of Psychology of the University of Moscow has, therefore, commenced the publication of a series of books and pamphlets on perception, observation, memory, emotions, etc., under war conditions, and the first booklet, by Prof. K. Kh. Kukcheev, deals with the psychophysiology of camouflage and of reconnaissance.

Detailed scientific data are given on such subjects as the sensitiveness of contrast vision ; stereoscopic vision ; estimation of distances ; perception of movement of different velocity ; colour vision ; visual perception at low light intensities in connexion with night reconnaissance ; physiology of sound perception ; sound 'camouflage' ; tactile perception and training for 'blind' action; olfactory perception and 'camouflage' of poison gases by other substances; etc. On every point, physiological facts and principles are briefly presented and illustrated by examples likely to be met on the battlefield.

The booklet is, apparently, not intended for immediate practical use; but rather to supply camouflage experts with the necessary data of physiological order.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Saturday, November 20

BRITISH RHEOLOGISTS' CLUB (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 2 p.m.—Commander C. F. Goodeve, F.R.S.: "Rheology and Naval Problems".

Monday, November 22

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. W. A. Robertson: "Timber—the New Outlook" (Cantor Lectures, 1).

Tuesday, November 23

ROYAL ANTHROPOLOGICAL INSTITUTE (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 1.30 p.m.—Prof. F. C. Bartlett, F.R.S.: "Anthropology in Reconstruction".

INSTITUTION OF BRITISH AGRICULTURAL ENGINEERS (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. S. S. McKay: "Mechanization in Farming".

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 4.15 p.m.—Discussion on "The State of Nutrition in Enemy-Occupied Europe" (to be opened by Colonel W. E. Vignal and Dr. A. P. Cawadias).

CHADWICK PUBLIC LECTURE (at St. Mary's Hospital Medical School, Norfolk Place, Praed Street, London, W.2), at 4.30 p.m.—Sir Harold Morris: "Sir Malcolm Morris, Dermatologist—Some Personal Reminiscences" (Malcolm Morris Memorial Lecture).*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5 p.m.—Mr. B. D. Richards: "Post-War Transport in Great Britain".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. J. C. Drummond: "Food Problems of the Post-War Years", 1: "Food Production".*

Wednesday, November 24

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. J. G. Davis: "Cheesemaking".

INSTITUTION OF ELECTRICAL ENGINEERS (WIRELESS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. C. P. Edwards: "Enemy Airborne Radio Equipment" (with demonstration of equipment).

Thursday, November 25

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Prof. W. Perceval Yetts: "Links between Ancient China and the West: a Study of Exchanges in Material Culture", 1: "Roads to the West".*

INSTITUTE OF FUEL (in the Engineers' Club, Albert Square, Manchester), at 3 p.m.—Dr. E. W. Smith: "The Aims and Objects of the Institute in relation to the National Fuel Position".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 3 p.m.—Dr. A. P. M. Fleming: Lecture to commemorate the Life and Work of Nikola Tesla (illustrated by examples of Tesla's experimental work).

BRITISH INSTITUTION OF RADIO ENGINEERS (LONDON SECTION) (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6.30 p.m.—Mr. M. M. Levy: "Stabilizing Electronic Circuits".

Friday, November 26

PHYSICAL SOCIETY (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 4.30 p.m.—Dr. H. T. Flint: "A Survey of Nuclear Field Theories".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5 p.m.—Sir Joseph Barcroft, F.R.S.: "The Preservation of Foods by Drying".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned;

ADVISER IN AGRICULTURAL CHEMISTRY—The Registrar, The University, Manchester 13 (November 23).

TECHNICAL ASSISTANT (second) in the Economics Department—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (November 24).

LECTURER (full-time) IN THE DEPARTMENT OF AERONAUTICAL ENGINEERING—The Registrar, Loughborough College, Loughborough, Leics. (November 27).

INSTRUCTOR (full-time) IN PLUMBING in the School of Building East Ham Technical College—The Secretary for Education, Educatio Office, Town Hall Annexe, Barking Road, East Ham, London, E. (November 27).

LECTURER (part-time) ON WORKS ORGANIZATION AND MANAGEMEN —The Principal, West Ham Municipal College, Romford Road, Stratford, London, E.15 (November 29).

CHIEF TECHNICAL OFFICER—The Secretary, Warwickshire Wa Agricultural Executive Committee, 6 Guy's Cliffe Avenue, Leamingto Spa (November 30).

PSYCHOLOGIST (with an Honours Degree in Psychology, experienc of testing, remedial teaching, and preferably child guidance work)—The Medical Superintendent, Central Mental Hospital, near Warwic (December 4).

DEMONSTRATOR (temporary, full-time) IN BIOLOGY—The Dean, St Bartholomew's Hospital Medical College, London, E.C.1 (December 7)

DEMONSTRATOR (man or woman) IN THE CHEMISTRY DEPARTMENT—The Warden and Secretary, London (Royal Free Hospital) School o Medicine for Women, 8 Hunter Street, Brunswick Square, London W.C.1 (December 10).

CITY ENGINEER AND SURVEYOR—The Town Clerk, Town Clerk' Office, St. Albans (endorsed 'City Engineer') (December 10).

FULL-TIME LECTURER (temporary) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Principal, Borough Polytechnic, Boroug Road, London, S.E.1.

LECTURER IN ELECTRICAL ENGINEERING—The Registrar, Merchan Venturers' Technical College, Bristol 1.

HYDROGRAPHICAL SURVEYORS for the Basrah Port Directorate Iraq—The Ministry of Labour and National Service, Appointment Department, Sardinia Street, Kingsway, London, W.C.2 (quotin Reference No. O.4962.S).

PROFESSOR OF PHYSICS, a PROFESSOR OF GEOLOGY AND MINERALOGY and a SENIOR LECTURER IN BIOCHEMISTRY, in the University of Melbourne—The Secretary, Universities Bureau of the British Empire c/o University College, Gower Street, London, W.C.1.

QUALIFIED METALLURGISTS for interesting work connected wit Powder Metallurgy—The Ministry of Labour and National Service Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. O.N.F.1212.X).

ASSISTANT MASTER (GRADUATE) FOR MATHEMATICS, SCIENCE AN DRAWING, in the Junior Technical School for Boys—The Director o Education, 8 Warrington Street, Ashton-under-Lyne, Lancs.

METALWORK INSTRUCTOR—The Principal, South Dorset Technica College, Newstead Road, Weymouth.

ASSISTANT IN THE BIOCHEMICAL DEPARTMENT—The Medical Superintendent, Dudley Road Hospital, Birmingham 18.

ASSISTANT METALLURGICAL CHEMIST for the Works Laboratory o an important Engineering Works near London engaged on highes priority Government work—The Ministry of Labour and Nationa Service, Central (Technical and Scientific) Register, Alexandra Hous Kingsway, London, W.C.2 (quoting Reference No. O.N.F.1669.X).

ENGINEER in the Directorate of War Production, Government o Palestine, and an ENGINEER in the Department of Heavy Industrie Government of Palestine—The Ministry of Labour and Nationa Service, Central (Technical and Scientific) Register, Alexandra Hous Kingsway, London, W.C.2 (quoting Reference No. E.804.A).

PROBLEMS OF INTERNATIONAL MINERAL CONTROL

MANY of us, uplifted by the Atlantic Charter, may take that resounding slogan "equal access to raw materials" as a product of the modern democratic spirit. It would be well to recall, however, that it was used by the Germans during the War of 1914–18, and was repeated between wars by the Italians, the Japanese and others until it became the rallying call of the 'Have-nots'. We may first inquire as to how grievous was the inequality of access which the Axis Powers and the poorly endowed nations felt they suffered from, so far as mineral raw materials were concerned. Answers to this question and to a great many more in mineral politics are provided by a recent publication[1] of the Brookings Institution of Washington.

The uneven distribution of minerals—a distribution which cannot be altered—undoubtedly bore especially heavily on the Axis Powers. It has to be admitted that, apart from the coal, magnesite and potash of Germany, the bauxite, sulphur and mercury of Italy and the sulphur of Japan, little of the immense bulk and variety of mineral raw materials necessary for large-scale industry was available within their own borders. It may here be interpolated that their mineral position is not materially improved even with their boundaries temporarily inflated. Interchange of mineral products, as of other products, is accordingly unavoidable; no dictator, by taking any quantity of careful thought, can make his country self-sufficient in minerals—a fact brought home by the realization that even gigantic associations like the three chief 'mineral Haves', the British Empire, the U.S.A. and the U.S.S.R., are not themselves completely self-sufficient, either alone or in any possible combination.

To what degree, then, has equal access been denied to the 'Have-nots'? As the authors of "World Minerals and World Peace" demonstrate by maps and statistics, mineral raw materials have moved in gigantic quantities throughout the world. It has been the major preoccupation of most of the great mineral cartels and monopolies to find markets. Indeed, many of these associations were formed expressly to expand their mineral sales. The Axis Powers were invited, and even enticed and persuaded, to buy Canadian nickel, American oil, Russian manganese, Malayan tin, and so forth. To all who were able to pay, there was equality of access to buy. The price could not be the same to all buyers, any more than manufactured goods are available to all on an equal-cost basis; the cost of transportation, considerable with the majority of mineral products, controls this. Further, equality of access, as distinct from freedom of access, was affected to only a slight extent by the working of the many varieties of trade barriers. Export tariffs provided revenue for the exploiting country, import tariffs were designed to aid a home production. These controls, with quotas, embargoes and the whole fiscal kindred, gave rise to friction between combinations of consumers and producers, but not between the 'Haves' and the 'Have-nots' as such. The removal of all trade barriers which are deliberately designed to offset the inequalities of mineral distribution would, as pointed out by Leith, Furness and Lewis, emphasize these inequalities and would contribute little to the solution of the general problem. These investigators conclude that most of the complaints raised by the 'Have-nots' arise from the strategic importance of minerals in time of war. Modern war is primarily a mineral war, and the relative poverty of minerals of the Axis Powers is a severe handicap to a career of aggression.

However dubious its origin may have been, the slogan "equal access to raw materials" has now become respectable and legitimized by Clause IV of the Atlantic Charter. The United Nations "will endeavour, with due respect for their existing obligations, to further the enjoyment by all states, great and small, victor or vanquished, of access, on equal terms, to the trade and to the raw materials of the world which are needed for their economic prosperity". It will be recalled that the Division for the Social and International Relations of Science of the British Association held a conference on Mineral Resources and the Atlantic Charter in July of last year. Among the findings[2] of this conference were recommendations which led the Council of the Association to appoint a committee, under the chairmanship of Sir Thomas Holland, "to enquire into, and report upon, the state of knowledge of mineral and metal resources, other than coal and petroleum, essential for modern industrial development from the point of view of the Fourth Clause of the Atlantic Charter". The report of this Committee has now been published[3].

The major problem of the Committee was taken to be to suggest methods for obtaining and keeping up to date the essential facts concerning mineral resources. The imperfections of our knowledge of the distribution of mineral deposits and the shortcomings of the statistics of mineral production and trade are clearly serious obstacles in the attainment of reliable data. The estimation of mineral reserves, even in well-surveyed ore-bodies, is at most times a hazardous proceeding. This applies with particular force to the reserves in certain fields which, though important, are worked by primitive methods. The Committee makes a plea for the classification of ore-reserves according to the degree of certainty of knowledge of them, and requests that the grade and quality of the ore shall, where possible, be specified. A distinction, and that a just one, is drawn between what a mining company might consider to be mineral reserves, that is, economically extractable ore, and what a nation might consider to be mineral reserves, which would include such resources that may exist but have not yet been brought under estimation.

The domestic resources of the United States are surveyed in comprehensive fashion by the National Resources Board. It is to be expected that the U.S.S.R. has exact information on its mineral production and its mineral deficiencies. The Committee advises that a similar survey of the mineral resources and capacity for mineral and metal productions of the British Commonwealth should be undertaken.
is to be hoped, the Committee continues, that af
this War complete data on world mineral producti
will be available for an international organizati
through the activities of the various national resour
boards. It is recalled that a mass of information
mineral deposits is buried in the confidential reco
of mining companies, while details concerning t
activities of the greatest mineral company in t
world, the U.S.S.R., are not yet published. T
Committee urges, therefore, that, following
conspicuous example of the United States, each c
venient national unit should establish a minerals a
metals resources board to prepare a detailed asse
ment of its own resources, so that an internatio
resources organization may be completely inform
It is further urged that reliable statistics of the qu
tity and grade of minerals used in each national u
must be available so that "the quantity of r
materials necessary for the economic prosperity o
country" may be assessed.

Among its conclusions, the Committee consid
that "there is sufficient information already availa
to permit the framing of a general policy designed
regulate the flow of essential mineral supplies, fr
countries in which certain of them occur in excess
domestic requirements, to others which are defici
in the natural products required for their essen
peace-time industries". The framing of this gene
policy is unfortunately outside the terms of refere
of the Committee, but it would have been interesti
and perhaps entertaining, to have had some guid
lines from so distinguished a body. It is only fair
recall, however, that the equally distinguis
framers of the Atlantic Charter clearly foreshado
a policy of mineral control, but have unfortunat
given us no clue to their plan. Is a plan possible
even necessary ?

There can obviously be no sharing-out of min
deposits, nor can there be redistribution of colo
sources, nor can territorial adjustments be mor
correct if based upon a mineral plan. We have s
that it is the opinion of the authors of "W
Minerals and World Peace" that up to now there
been equality of access to buy for all who could
May not this very equality of access have been
root cause of the present troubles ? Equality
access is excellent for a concourse of peaceful nat
engaged in their lawful pursuits, though even
conflicting national needs may give rise to fricti
but equality of access has hitherto allowed though
aggressors to acquire and pile up stocks of
minerals in preparation for 'the day'. They h
moreover, been able to pay for them in many c
only by very questionable operations. This is
fundamental problem arising from Clause IV: s
it is clearly just that all nations should have e
and unrestricted access to minerals for peaceful e
by what devices can it be assured that minerals
not diverted to war-like purposes ? The furnish
of the 'reliable' statistics of each country's peace-t
requirements of minerals required by the Bri
Association Committee would, we may be sure,
little bother to a potential aggressor. There is

course, an excellent and infallible method of solving the problem, and that is to have no wars or, in other words, to prohibit armaments. Who will prohibit, and by what armament is the prohibition to be enforced ?

This matter of mineral control in relation to peace has engaged the attention of Prof. C. K. Leith of the University of Wisconsin ever since the War of 1914–18. Prof. Leith contributes a short final chapter on this topic to "World Minerals and World Peace". It is of interest to recall that plans for the allocation of the Allies' surplus mineral products among the defeated nations were prepared for the Paris Peace Conference ; their serious discussion was prevented, most tragically, by devotion to other and less worthy topics. Realizing that the sanctions against aggressor nations provided for in Article XVI in the Covenant of the League of Nations were much too comprehensive to be effective, Sir Thomas Holland proposed in 1929 his 'Mineral Sanction', whereby the export of mineral products to any country breaking the peace was prohibited. As we see it and with regard to this present conflict, a fairly complete mineral sanction is in operation ; the aggressors had, however, effected the obvious insurance—they had piled up enough spark-plugs to make sure that the tank would run for some time.

Leith is of the opinion that two primary requirements must be met to prevent stock-piling for war :

> "The *first* is that there must be preponderant possession of the world's mineral resources by those who elect to prevent would-be aggressors from storing up supplies.
>
> "The *second* is that machinery for the control of minerals must be in operation *prior* to the actual outbreak of war."

The mineral resources of the United Nations are at least three times as great as those of the Axis, and, with continued exploration, the factor will undoubtedly increase. The United Nations, therefore, *could* operate a mineral control. Such a control should be administered as a trust to ensure that minerals are allocated to nations in accordance with their needs for peaceful ends, and for these only. Its effective operation so that no stock-piling takes place would require supervision of various kinds—supervision of imports, supervision of uses, supervision of every phase of industrial activity. It would require also the closest co-operation between the countries producing minerals and an astounding lack of selfishness in nations and nationals. It would require, in other words, honesty among nations. Possibly some form of cartel for each mineral product, with an international governmental backing, might provide a reasonable middle course between complete nationalization or internationalization and the present structure of the mineral industry.

Leith, with the experience of the application of sanctions to Italy and of other episodes in the history of the League of Nations before him, pleads for planning *now*. He realizes, as the framers of the Atlantic Charter did not, that the use of force may be necessary for the working of any mineral control plan. Let us not confuse force with violence.

The greatest obstacles to the enjoyment of the natural wealth of the world by its owners, the people of the world, is that ancient and foul trinity which becomes more powerful with what we used to call progress—the trinity of ignorance, greed and fear. Physical planning with the head cannot remove the obstacles ; spiritual planning with the heart may, for, after all, most of them are simply the consequences of plain sin.

RECONSTRUCTION OF ENGINEERING EDUCATION

RECONSTRUCTION plans for many branches of national activity are under discussion, and it is of the greatest importance that every grade of education should be examined critically, since the influence of changes, whether for good or ill, will certainly be more far-reaching in this sphere than in any other.

It is therefore eminently right that professional bodies should give immediate attention to the education of future recruits to their professions, and the Council of the Institution of Mechanical Engineers is to be congratulated on the timely publication of its considered views on this important subject[1].

The Institution claims, rightly, that it has a national responsibility, by virtue of its charter, for the maintenance and enhancement of the standard of education of all grades of mechanical engineers, and in discharge of this obligation it has for some time been giving attention to educational problems. The publication of the White Paper by the Board of Education provided an appropriate occasion to place on record the major conclusions which have emerged from the Institution's discussions.

The Council of the Institution speaks with authority, and although, as is proper, its report specifically relates to problems connected with the training of mechanical engineers, it may be said at the outset that much of it is equally applicable to other branches of engineering. The report is comprehensive, and will repay close study by those interested in this vital question—which should include all who are concerned in any way with the future efficiency and professional status of the engineer.

It is impossible to deal here with all the topics considered and the questions raised by the Report but some of them, at least, may be appreciated if we attempt to trace the educational path of the young engineer of the future who desires a university training, after the reforms suggested have been implemented. At the age of sixteen, having made up his mind to become an engineer, he will be faced with the first decision ; whether to remain at school for another two years or to begin a works training. The answer may depend partly on economic considerations, but not so much as if he were living in the pre-war world, since there will be a well-considered plan of State bursaries to ensure that all suitable candidates can enter their chosen professions. Perhaps the determining factors will be his aptitude for study and his personal predilections. If he is anxious to start practical work at the earliest possible moment he will, for three years, follow an organized training in works and technical college, being released for part-time day-work in the latter; this period will include any national service to which he is liable. He will then, at the age of nineteen, be ready to enter the university, where he will find the matriculation requirements more consistent with his previous education and experience than they were for his predecessors. At this stage he will, perhaps, meet an old school-fellow who remained at school and obtained the Higher School Certificate, or its post-war counterpart. This school-fellow will have served a year in part-time instruction in works on a national service basis and will now also be ready to begin his academic career. Both of them are State bursars and are therefore not handicapped by accident of place of residence or by lack of private means from securing their education.

The choice of university will not be a matter even of such importance as it is to-day, since the diversities of practice in regard to courses and custom which now exist will have been largely eliminated; one difference in particular will vanish—wherever our young men study they will need an extra year if they are not content with pass degrees but desire to obtain honours. (In this connexion the Report is not quite clear whether the Higher School Certificate will exempt from the pre-intermediate year as at present, that is, whether the two will start level in their academic careers.) Their experience in works will have given them a certain critical faculty, and this will be exercised on the teachers and equipment provided for their instruction. These will be found to be above reproach. The teachers will be, and will remain, engineers who have been trained to teach and are 'refreshed' at intervals either by a return to industry for a period of three months in each year for several consecutive years, or in some cases for a complete year at a time. These teachers will be paid adequately, and their prospects will be comparable with those which would have been open to them if they had followed industrial careers. Not only will they be kept up to date in the practice of their profession, however, but by means of refresher courses at a postgraduate college they will be kept in touch with the newest scientific developments in particular subjects; they will, moreover, add to these developments by their own researches, for which time will be made available and, in addition, will assist local industry as consultants in their specialized subjects. Finally, they will be encouraged to take part in the various activities of the professional institutions, and this will indeed be part of their regular work, for which they will be entitled to recover expenses from their governing bodies. At intervals our young undergraduates will miss some of their accustomed teachers for a time as they will have exchanged posts temporarily with their opposite numbers in universities either in Great Britain or abroad.

The equipment of the laboratories will be representative of modern practice and will be kept up to date by industrial organizations and associations Here perhaps one may be allowed to express some doubt as to whether this proposal is the best possible or even to be advocated. It will readily be agreed by those who know the conditions of many engineering laboratories that the standard of equipment i often "deplorably low", as stated in the Report, bu it is doubtful whether in most cases general engineering machinery is suitable for instructional purposes Specially designed plant is usually necessary i essential principles are to be taught, even perhap at the expense of some lag behind latest industrial development. Doubt may also be expressed as to whether the "range of basic knowledge" is expanding quite as continuously as the Report suggests—applications certainly are doing so, but in teaching the undergraduate it may be wise to draw a distinction. Basic knowledge is the proper scope of undergraduate studies; special developments appear more properly in postgraduate courses.

During long vacations, students will be expected t spend at least eight weeks in gaining practical experience of one sort or another, and this will be arranged for them by their university co-operating with employers in industry.

In due course our students graduate and will then complete their practical training by spending sufficient time in works to bring the total period of work training up to not less than two years. If they wish to continue their academic work they can do so by spending one or two years in advanced study or in research, and the Report makes the suggestion tha students of one institution should be allowed to do this at another which has specialized in a particula field. This is already done in many instances, but the principle might well be extended, even to the extent of making the Ph.D. degree of one university available only to postgraduate students from others; this would be in close accord with the original intention behind the establishment of this degree.

In some respects the proposals are not seriously dissimilar from existing conditions in many universities, but they are very far from those which obtain in technical colleges, particularly as regards the conditions of employment of staff, teaching hours and encouragement of research. In this last connexion the Report in no way overstates the case when in commenting upon the adverse effect upon superannuation of time spent on work other than teaching it says "A more effective way of discouraging research would be difficult to imagine". It is the desire of the Institution that technical colleges, as well as universities, should conform to the standard suggested and it would like to see more full-time students in the technical colleges. It is stated tha there is room in industry for a greater number o men of graduate rank than can be supplied by th universities and that suitable technical college should provide to a greater extent than at present full-time courses of degree standard.

This is open to discussion; it may well be argue hat the work of the universities and the technical olleges should be differentiated, rather than identiied, and that they should be training men for ifferent kinds of equally important work. If that vere conceded, it might be necessary to extend to ome extent the facilities in the universities, but still more probably it would entail a substantial increase n the provision for training in technical colleges. At present there appears to be a tendency for the universities and the technical colleges to overlap unnecessarily, and it cannot be an economical or fficient use of resources when, in the same limited rea, a university grants its own degrees and one or more technical colleges prepare for degrees of another university. There is certainly enough work for all o do, but not necessarily of the same kind.

This article has concentrated on those sections of he Report which deal with the university training f engineers; many other important topics are xcluded by lack of space. Practical training, for raftsmen as well as professional engineers; courses n technical colleges for craftsmen; and the allocation f available funds for educational reconstruction; are lso discussed in the Report. On the last, a feeling of disquiet is expressed that the Board of Education laces undue emphasis on "Buildings" as the end of ll technical educational reform. It is to be hoped hat the powerful influence of the Institution of Mechanical Engineers will be reinforced by that of ther interested bodies to prevent this fear being ustified by the event.

EDWARD TYSON, 1650–1708

dward Tyson, M.D., F.R.S., 1650-1708, and the Rise of Human and Comparative Anatomy in England

A Study in the History of Science. By Prof. M. F. shley Montagu. (Memoirs of the American Philoophical Society, Vol. 20.) Pp. xxix+488. (Philaelphia: American Philosophical Society, 1943.) dollars.

THE keynote of this book, as provided by Prof. Montagu himself, is an unbounded and emotional nthusiasm for its subject. Now enthusiasm may be good and a beautiful thing, but if the enthusiast ndulges in frequent and generous outbursts of it, his ision becomes blurred, and his opinions, to quote Mr. Sampson Brass, tend to verge upon the confines f injudiciousness. For example, Prof. Montagu entures to bracket Tyson with Copernicus, Vesalius nd Newton—a proceeding which the sober historian an regard only as a symptom of mental obscuration. Again, Tyson's competent but modest paper on the natomy of the rattlesnake is described as a study of reptile which has never been equalled before or ince; his anatomy of the opossum "has scarcely ver been excelled"; his demonstration of the relaions of apes and man (not even mentioned by Darwin) an "epoch-marking event" which "exercised a proound influence upon the intellectual development of he eighteenth century"; his research scheme is "one of the finest expositions of the method of comparative anatomy which has ever been written"; his description of the anatomy of the porpoise was such "as had not before been given by anyone of the anatomy of any animal", and so on. Such statements cannot be justified, and do not even enhance the importance of Tyson's genuine achievements, which could have been less picturesquely stated without detracting from their legitimate claims on our admiration. Prof. Montagu should take to heart the wholesome advice of De Quincey—not to sink over head and ears in love, but to leave afloat a trifle of brain to overlook the whole conduct of the affair.

To complete the ungrateful task of criticism, we must regret that Tyson's valuable contributions to comparative anatomy, published and unpublished, are not critically examined and assessed, in consequence of which the reader is not advised what exactly Tyson had discovered, and to what extent he had corrected and extended the labours of his predecessors and contemporaries. This task, therefore, has still to be accomplished. Even Tyson's well-known work on the chimpanzee is not adequately analysed from the *anatomical* point of view, although such an undertaking would have been well within Prof. Montagu's competence as a professor of anatomy.

The merit of this work, therefore, lies in what Prof. Montagu has to tell us of Tyson's life and cultural environment, and here he has much to say that is new and of undoubted value. This part of the monograph would have been even more impressive had not the War cut short his last visit to England before his researches were completed. This affected particularly the work on the Tyson manuscripts preserved in the Royal College of Physicians and the British Museum, which naturally can be studied only in those institutions. The records of the Royal Society include much Tyson material, of which Prof. Montagu has made the fullest use. As a craftsman Tyson cannot be compared with Casserius, Malpighi and Swammerdam; but his scheme for the promotion of a science of comparative anatomy, which he did not live to implement, shows that he had a more prophetic and philosophical outlook than his seventeenth-century contemporaries. Prof. Montagu is particularly admirable on this theme, as he is also in his essay on Tyson's remarkable monograph on a young chimpanzee, although here Tyson owed much to the assistance of Cowper, and in his other work to Waller. Not much is known of Tyson's life, but Prof. Montagu seems to have exhausted all possible sources, and it is therefore scarcely likely that we shall ever know more. His account of the history of the skeleton of Tyson's chimpanzee, now in its final resting-place in the British Museum, is particularly attractive. An extensive, and with few exceptions accurate, bibliography is appended.

Prof. Montagu appeals for corrections, and here are a few of the more relevant points which have been noticed in reading this original and important work. Pp. 50–1: Attention is here directed to an unusual bibliographical problem. Tyson has been credited with having published in 1669 a work on the *Rhymes* of the Ancients. This, as Montagu rightly points out, is a mistranscription of the *Pygmies* of the Ancients of 1699, but the mistake has been extensively repeated in various bibliographies. Montagu ascribes the error to Munk in 1878, and severely criticizes him for it. Who first started this bibliographical hare the present writer is not prepared to say, but it was certainly not

Munk, who simply copied it word for word from Watt's "Bibliotheca Britannica" of 1824. P. 58: Redi 1671. There is evidently some confusion here. The work by Redi is not correctly quoted or described, nor was it translated by Waller. P. 122: "Jan Jocoboz [Jacobsz.] Swammerdam" was Swammerdam's father. P. 137: Tyson's Faithorne was the father (1616–1691), not the son. Pp. 152–3: The tapeworm described by Tyson was *Taenia pisiformis* of the dog, of which he examined the external characters only, and, even so, unaccountably failed to observe the suckers of the scolex! He does *not* give us a minute and perfect description of the anatomy of the worm. The worm figured on p. 153 is obviously not a Bothriocephalid but a Taeniid—probably *Taenia saginata*. P. 161: *Rana piscatrix* is not a frog, but the fish *Lophius piscatorius*. P. 169: Tyson cannot be acquitted of the belief that the peccary had three stomachs. His language is unmistakable, and he even compares the three stomachs of the peccary with the single stomach of the common pig. Pp. 184 and 388: Tyson did *not* discover the cochineal fly. His figures represent one of the Coccinellid predators of that insect. P. 196: Hartmann recognized the animal nature of hydatids in 1685 before Tyson. P. 211 and also bibliography and index: Powers is the possessive case of Power. P. 283: The progressive diminution of the thymus during life was known to Galen. P. 327: Neither Tyson nor Hale discovered the human allantois, judging from Hale's paper. P. 357: Tyson's "yellow gurnard" was *Callionymus lyra*. P. 382: Perrault's philosophical views on comparative anatomy do not appear in the Parisian memoirs, but in his "Essais de Physique", and they compare very favourably with those expressed in Tyson's "Preliminary Discourse". P. 390: Grew (1675 and again in 1681) was the first to use the expression comparative anatomy in the title-page of a book. P. 408: In the Opera Omnia of Tyson, published in 1751, the unsold copies of the first and only edition of the anatomy of the Pygmie of 1699 were bound up with reprints of Tyson's other works. A comparison of the two "editions" of the Pygmie work shows that they are absolutely identical in every respect, and the relative scarcity of the 1751 edition is due to the small number of copies of the Pygmie which were available for this issue.

F. J. COLE.

ADVANCES IN BIOCHEMISTRY

Annual Review of Biochemistry

James Murray Luck, Editor; James H. C. Smith, Associate Editor. Vol. 12. Pp. ix+704. (Stanford University P.O., Calif.: Annual Review, Inc., 1943.) 5 dollars.

THIS, the twelfth volume of the "Annual Review of Biochemistry", is a remarkable production in that it shows so little evidence of war and all that war is meaning to the scientific worker. We need not recapitulate the difficulties which face the research worker; easy exchange of information and of publications is a thing of the past, and the censorship and import regulations have added greatly to the difficulty of our getting much-needed scientific books from the United States. In those many sections of scientific activity which make up biochemistry, the "Review" is more than ever useful in keeping us in touch.

The volume contains the usual articles on progres in what may be termed standard sections of th subject, but we would direct attention more partic larly to the sections in the latter half of the volum as examples of its utility. Experimental progres waits largely on an advance in technique such as afforded by the recent development of microchemic methods: it is affirmed that chemical behaviou remains essentially unchanged when only 10^{-8}–10^{-} gm. of matter is used. The section describing th developments in these methods is most helpful.

There is a report for the first time on the electro microscope, which has progressed rapidly since th building of the first compound instruments te years ago.

In the study of the biochemistry of micro-organisms there has been a striking shift in emphasi changing to the study of microbial nutrition fro that of metabolism. Many growth-factors have bee identified with typical vitamins, so that the result have a direct bearing on the nutrition of highe organisms. The report includes a summary of wor on anti-bacterial agents such as the sulphonamide and penicillin. Synthesis of vitamins by culture o Torula yeast on wood-sugar and other industri wastes has been known for some time, and such wor is being extended.

The demonstration that plant viruses are protei macro-molecules brought the chemist and the physici into this field. The review describes the formatio of acetyl and phenyl-ureido derivatives of tobacc mosaic virus and their inoculation into susceptib hosts. The experiments are thought to show tha infecting virus molecules may not necessarily func tion as exact patterns for reproduction, while a larg proportion of certain functional groups of the viru molecule may be changed without appreciably alte ing the virus activity. There is much work o tobacco mosaic virus, including the determination its constituent amino-acids.

No subject is more to the fore to-day than nutr tion, and there is a stimulating report on it. I Great Britain much is being done to persuade a co servative and ignorant public to eat the proper thing and there is a marked change for the better in gener health in consequence. The value of an improved die during pregnancy on the course of pregnancy, labou and convalescence of the mother and on the gener well-being of the baby is firmly established, an action has been taken to make it available her For the masses the lack of oranges and othe fresh fruits is a serious disability; the vitamins lo are only very partially made up from vegetable which are very hard to obtain fresh in the citie where they are most needed. Vegetables also a far too dear, almost beyond the purse of many, an it is a reflection on the Ministry of Food that whil recommending us to eat more vegetables we are n safeguarded against extortion.

Space restricts any more detailed reference to th other sections, though we may mention the stead but slow progress in the study of the proteins. Th is difficult and somewhat unfashionable work, b we are behind in our knowledge. In discussing t sugars, emphasis has been placed upon the effect unsaturation in directing and influencing not mere carbohydrate reactions but also biological reactio in general.

The editors and their helpers are to be congratulate on a most useful piece of work.

E. F. ARMSTRONG.

A Text-Book of Organic Chemistry

Historical, Structural and Economic. By Prof. John Read. (Bell's Natural Science Series.) Third edition. Pp. xiv+703. (London: G. Bell and Sons, Ltd., 1943.) 12*s.* 6*d.* net.

PROF. READ has taken advantage of yet another reprinting of his deservedly popular book to keep the subject-matter abreast of current advances. Although the operation had to be effected without upsetting the pagination, considerable ingenuity has been exercised in the successful execution of this delicate task. Without such restrictions the author would undoubtedly have made extensive alterations and additions, as a piecemeal revision of this type can never be entirely satisfactory. It is therefore not difficult for the reviewer to direct attention to a number of desirable additions and deletions, although t may be somewhat unfair in the circumstances. In particular, some mention of crotonaldehyde and the ethanolamines, both of which combine theoretical with industrial interest, might have been made; less emphasis could have been given to wood distillation as an industrial process, and the fact that a number of sex hormones have now been isolated and their tructures determined could have been noted. In view of recent developments in the United States, it s unfortunate that the expression "the nitroparaffins have little practical importance" should have been allowed to remain. It might be pointed out that vitamin A has now been obtained in crystalline form and that the vitamins of the B, E and K groups are sufficiently well characterized to deserve passing mention.

None of these omissions, however, detracts seriously from the unquestionable value of this fascinating reatment of organic chemistry. On the contrary, the useful revision of the sections on petroleum and the electronic theory of valency, the latter including some discussion of resonance concepts, the inclusion of a modern formula for a polysaccharide and references to sulphanilamide, *M* and *B* 693 and to the electrophoresis of proteins, to mention just a few points, combine effectively to bring this reprinting up to date.

E. R. H. JONES.

Intermediate Chemistry

By Prof. T. M. Lowry and A. C. Cavell. Third edition. Pp. xvi+876. (London: Macmillan and Co., Ltd., 1942.) 12*s.* 6*d.*

FIRST published in 1936, and revised in 1938, this excellent book has again been brought up to date y alterations in several important sections—in particular those dealing with carbon monoxide, the rusting of iron, the distillation of liquids, organic analysis, and the organic derivatives of ammonia. Many additional numerical problems have been provided, and improvements in the experimental sections—nearly two hundred of them—have been introduced.

Its purpose being "to provide a complete text-book f chemistry for Intermediate and Higher School ertificate examinations", the volume is accordingly ivided into six parts, headed, respectively, general nd theoretical, typical elements, transitional elements, analysis, physical chemistry, and principles of rganic chemistry. True, a candidate for one of these xaminations who had fully mastered its content ould be remarkably well prepared; but wise achers who tolerate examinations, and conscientious udents who utilize them, are likely to discern in this ery circumstance the real aim of the authors. This, quite evidently, is not merely to elongate any pass list, but to help to lay a solid foundation of accurate chemical knowledge and intelligent appreciation; a foundation which retains familiarity of design while providing truly adequate footings for the support of a necessarily weighty building in the modern fashion. Though described as an examination text-book, therefore, it is not a cram book. Indeed the authors, when discussing the habit of the individual trees, frequently direct attention to one or other aspect of the wood; and this serves to promote a balanced view and to maintain a sense of orderliness which contributes much to the reader's interest and holds his attention.

Chemical Industries

Edited by L. Ivanovszky. Eighteenth edition, largely rewritten and revised. Pp. xxiv+360. (London: Leonard Hill, Ltd., 1943.) 15*s.*

IT would be difficult to arrange the experimental sciences in an order that would tally with their relative importance in everyday life, but chemistry would undoubtedly occupy a very high place. Far away and long ago their applications played a very minor part; here and to-day they are almost indispensable. It is true that these applications relate very largely to the material side of our daily life, but unless we go forward with the march of civilization, look to increasing our wants as well as our needs, and extending our comforts, we shall fall behind as a progressive people and sink into the limbo of the 'have been'. These reflexions arise from a perusal of the latest edition of Leonard Hill's "Chemical Industries", which is replete with the information required by manufacturers, merchants, consumers, and by those numerous 'impure' chemists who traffic in the applications of their science to material human wants. This new edition is considerably larger than the old. The glossary of industrial chemicals has been increased by more than one half; the tables of physical and chemical constants have been revised and extended, and many new data concerning organic and inorganic compounds have been added. Further, entirely new subsections are incorporated dealing with metals and alloys, non-metallic materials, chemical plant and instruments, and the older ones on pharmaceuticals and perfumery raw materials have been replaced by new. Power plant, water-treatment, handling, conveying and transport are other sections of this very useful compilation.

E. H. T.

A System of Qualitative Inorganic Analysis

By Dr. J. L. B. Smith. Second edition. Pp. viii+64. (Cape Town, Bloemfontein and Port Elizabeth: Nasionale Pers Beperk, 1943.) 4*s.* 6*d.*

THIS work on qualitative analysis is intended purely as a laboratory manual, since the physico-chemical principles underlying analysis are not discussed and very little is said about the nature of the chemical reactions involved in the tests. These omissions, together with the use of a very large number of abbreviations, give the text rather a forbidding appearance, and the reader the impression that qualitative analysis is purely a mechanical operation of adding so much of one substance to so much of another. The book, however, contains some notable features which deserve consideration by students of advanced chemistry. Thus a systematic scheme has been worked out for the detection of all the common anions, and very precise details have been provided throughout for carrying out the tests under the right physical conditions. In choosing the tests the author has guarded, so far as possible, against the mutual interference of ions, and this is typical of the care he has taken throughout to ensure success to the user of his system of analysis.

A. C. C.

A Dictionary of the Fungi

By Dr. G. C. Ainsworth and Dr. G. R. Bisby. Pp. viii +360. (Kew: Imperial Mycological Institute, 1943.) 20*s*.

FOLLOWING the lines of Willis's well-known "Dictionary of Flowering Plants and Ferns", Ainsworth and Bisby have included in their 339 pages a mass of useful information. In addition to generic names, with a reference to the family and a brief note as to habitat, they have provided explanations of technical terms, though unfortunately without their derivations. Students with "little Latin and less Greek" may be puzzled, for example, to find under *plano-* both planogametes and planoconvex, even though the terms *plane* and *planetism* are defined in the preceding lines. Useful notes are given on some of the older mycologists, and such popular terms as *devil's snuffbox* are not disdained.

It is perhaps inevitable that, in a work of this kind, detail should be uneven. Thus under *sex* one learns that Pyronema—that classical fungus—has a trichogyne but not that it has an antheridium, though the non-motile sperms of the Laboulbeniaceæ are mentioned and both trichogyne and antheridium are illustrated in Fig. 54.

An interesting detail is that the book (apart from its appendix) is written in Basic English, but the simplicity which this suggests is lessened by the mass of technical terms. Comparatively few of those who look up the meaning of *metula* will be much wiser when informed that it is "a sporophore branch having phialides". It could be described nearly as briefly as "a branch bearing spores on flask-shaped outgrowths". The explanation of even superfluous technical terms may be of value, but their use is to be deprecated. Mycology is burdened with far too extensive a vocabulary, and the only serious criticism of this convenient little book is that it may revive words which were mercifully becoming obsolete.

Map Projections by Practical Construction

By A. Hinckley. Pp. 84. (London: George Philip and Son, Ltd.; Liverpool: Philip, Son and Nephew, Ltd., 1942.) 3*s*.

FOR students of limited mathematical ability, books on map projections usually have an arid and unattractive appearance. This little book—which assumes only an elementary knowledge of mathematics and provides simple practical constructions for a large number of projections, together with many exercises that bring out the value for many purposes of the study of the subject—is notably unusual in its treatment, and has the commendation of no less an authority than the secretary of the Royal Geographical Society. There is no doubt that the teacher of mathematics or geography—especially of the former—who is reasonably emancipated from examination limitations, will find in this book ample scope for much valuable work, and any student who follows it diligently will not only solve a large number of interesting mathematical problems but also acquire a considerable practical knowledge of the geographical applications of the study of map projections.

For the student of geography, who is primarily concerned with the selection of the most appropriate projection for any particular geographical purpose the book is, however, somewhat limited in being severely practical. Both teacher and student would appreciate a clear preliminary presentation of the problems involved in mapping the globe, and a systematic discussion of the relative value of different projections for different purposes, in addition to the incidental comments that are found in the book. At the same time it is recognized that the numerous excellent exercises cover a wide range of matters of interest and importance to the geographer.

L. S. S.

Simple Experiments in Biology

Compiled by Cyril Bibby. Pp. xii+164. (London and Toronto: William Heinemann, Ltd., 1943. 7*s*. 6*d*.

THE author of this useful book is education officer of the Central Council for Health Education, and joint editor of *Biology*. He is therefore very well acquainted with the practical needs of biology teachers, and the guidance they require. No specialized knowledge on the part of the teacher is assumed and no expensive apparatus for experiments is required.

The book is essentially practical; the theory being left to the more orthodox text-books. Descriptions are explicit, and the whole course is comprehensive The only criticism we have is that, although ther may be several reasons for not inserting an inde in this type of book, we still think its omission is t be deplored.

It is doubtful if there is any other book quite lik this, and we would strongly recommend its adoption in all classes of biology up to, and including, schoo certificate standard.

Hermaphroditos

The Human Intersex. By Dr. A. P. Cawadias. Pp ix+78+9 plates. (London: William Heinemann (Medical Books), Ltd., 1943.) 15*s*. net.

THE intersex or free martin has always been subject of great interest in medicine, in literature and in mythology. Dr. A. P. Cawadias develops his scheme of classification of androgynoids and gynandroids from a basic description of the physiolog of sex formation and of the physio-pathology of intersexuality. Case-histories and illustrations of th various types of abnormalities are given, and ther are some notes on the lines of treatment.

Studies on Immunisation

First Series. By Sir Almroth E. Wright. (Researche from the Inoculation Department, St. Mary's Hospital, London, W.2, Vol. 3.) Pp. xi+421. (London William Heinemann (Medical Books), Ltd., 1943. 25*s*. net.

THIS third volume in a series of the collected researches of Sir Almroth Wright contains reprints of papers on work done in the first decad of this century and originally published in 190 The survey covers the antibacterial elements of th blood fluids, agglutinins, bactericidins and opsonins and proceeds to vaccine and serum therapy.

POST-WAR NUTRITIONAL RELIEF IN EUROPE

THE English Group of the Nutrition Society discussed the "Scientific and Medical Aspects of Post-War Nutritional Relief" at a whole-day meeting held at the London School of Hygiene and Tropical Medicine on November 6. Lord Horder, who took the chair, remarked that the programme spoke of the scientific and medical aspects of the problem, not of the political, and he would endeavour to see that this intention was carried out. He sketched he contents of the official document setting forth the benefits which the United Nations Relief and Rehabilitation Administration (UNRRA) would confer on the nations whose representatives had subscribed to the document. Each of these nations is to be represented by one member on a Council which is o meet at least twice a year. In Lord Horder's opinion there is a gap in the machinery in the lack of a Supreme Economic Council to plan co-ordinated supply, and he thinks that the relation between the military administration of relief and the Relief and Rehabilitation Administration needs defining.

Conditions in Europe

Experiences of the War of 1914–18 and since, and the current state of nutrition in occupied Europe and elsewhere, were discussed by Prof. J. R. Marrack London Hospital and Committee for Co-ordination of Nutrition Surveys). During and after the War of 1914–18, the shortage of food was due much more o the neglect of agriculture than to the blockade. The total production of cereals in continental Europe was reduced by one third, and did not again reach the pre-war level until 1924. Livestock was reduced o 30 per cent in Poland, and the animals everywhere were very much underfed. The milk supply in Germany was 30 per cent of the pre-war amount. Freedom to trade was not restored to the ex-enemy and adjoining countries until April, and, in the case of Germany, until June 1919. Transport was hopelessly dislocated and local fighting still going on. Special machinery had to be set up or 160 million people would have been faced with great privation. All supplies provided by such special machinery were classed as relief and were almost entirely supplied by special credits, chiefly from the United States, or paid for in cash by the Governments of the recipient countries. Distribution was through the normal channels of trade, co-operatives or local authorities. Food was supplied in this way to twenty-one countries with a population of 230 millions, but relief was not continued after September 1919, except to children as canteen meals financed by charity.

The quantity of supplies imported into the countries other than the Western Allies and the neutrals was considerably less during 1919 and 1920 than during 1913, although food production was so much reduced. Only those children who showed signs of under-nourishment were fed, and these, at the peak periods in April 1920 and 1921, numbered, respectively, 3¼ and 2¾ millions. A large proportion also of adults must have needed more food and, though suffering was reduced by it, the relief sent was inadequate and stopped too soon.

Of the supplies sent, 60 per cent was flour and grain, though qualitatively, meat and milk were much more needed. The supplies sent for the children included food in unfamiliar forms which was often refused. The inadequacy of the relief is shown by the amounts of supplies to other countries. The total relief supplied in the five years, 1919–24, was less than the sum of imports of wheat and flour, meat, bacon, ham and sugar, into the United Kingdom in the one year, 1918. Similarly, the amount of pork products was less than one tenth of the total consumption of pork products in the United States in 1919. Only surplus products were sent as relief, regardless of their suitability, and, if food had continued to be rationed in Great Britain alone, far more would have been available for relief.

After the immediate post-war period, the Russian famine occurred in 1919–22, in which three million people died of starvation; this should be taken as a warning of what may occur if adequate preparation is not made. It is unfortunate that Dr. Melville Mackenzie has written of choosing which age-groups of the population should be fed and which left to die, as if this choice was inevitable and not a sign of failure.

When the present state of affairs is considered, the fact that food is rationed over most of the continent of Europe makes it possible to estimate that the average normal consumer is not getting more than 1,400 calories daily. The degree of deficiency varies from Greece, Poland and Spain, where the daily intake is less than 1,000 calories, to Germany, where it is about adequate. The deficiency of animal products is severe owing to slaughter of livestock. The effect of lack of food is seen in the increased death-rate from tuberculosis, which was a marked feature of the War of 1914–18 also. Some cases of famine œdema have been reported from Belgium. Rickets is said to be controlled by widespread distribution of vitamin D. The large amount of potatoes being grown should ward off scurvy. Fortification of the margarine with vitamins should prevent vitamin A deficiency if the supply of vitamin A holds out, but disruption of the transport of green vegetables may increase the risk. Use of flour containing a very large proportion of the whole grain should prevent gross deficiency of the vitamin B complex except in the maize-eating countries. This is the picture in Europe. From China we have little information, but the situation there may be the worst of all.

Surgeon-General K. Evang (Public Health Services, Norwegian Ministry of Social Welfare) stated that after the War of 1914–18 the most outstanding shortage was that of fats, the craving for which caused the greatest suffering. Rubner directed special attention to the effect of semi-starvation in causing mental deterioration, lethargy and indifference. In Denmark the exportation of butter caused the appearance of some hundreds of cases of blindness from vitamin A deficiency, but this only lasted until the blockade prevented the export of butter. It was very remarkable that the increase in the death-rate from tuberculosis, which was so marked in many parts of Europe, was in Vienna relatively greater among the better classes, because the deterioration in their food was relatively so much greater.

In the present War, production has not been so greatly reduced. The area dominated by the Germans is much larger and richer, and the Germans themselves are unlikely to suffer deprivation. Their food policy has not been the same in all countries; they have not looted them all and have even imported food into some.

The addition of 600 calories daily proposed as relief is not to be regarded as sufficient supplement to the average existing intake of 1,400 calories, though it can be used as a working basis. It is unfortunate that there is no criterion for the onset of a dangerous state of malnutrition except the returns of morbidity and mortality. The state of nutrition of political prisoners in the hands of the Gestapo must be very bad, since they are not treated as prisoners of war and may not receive parcels. There have been marked rises in the number of cases of poliomyelitis, cerebrospinal fever, erysipelas, diphtheria, pneumonia, scarlet fever, gastro-enteritis and scabies.

In practice, calories should be supplied first as grains and fats. Treatment should be just, as between the hungering nations; but justice should remember the differing peace-time standards of the various countries, and no country should be offered smaller rations than under the Germans. The supply of sea food in Norway could quickly be increased by a supply of new fishing equipment. All plans must be dominated by considerations of transport, production and the needs of economic warfare.

Dr. Geoffrey Bourne (University Laboratory of Physiology, Oxford) gave a sketch of the number of calories supplied as rations in the different countries in 1942. No attempt has been made by the Germans to feed the Russian civilians at all. The occurrence of anæmia and hunger œdema, and of deficiencies of vitamins C and D, calcium and riboflavin is anticipated.

Post-War Agricultural Production

Problems of production in relation to post-war nutritional relief were dealt with by Dr. J. Hammond (School of Agriculture, Cambridge, and Inter-allied Technical Advisory Committee on Agriculture). He pointed out that the manner of administration of relief will depend on whether countries are liberated separately, or together, and how far they have been destroyed. The shipping position will be of primary importance. The first phase must be based on supplying in all countries the minimum requirements needed for human life before any one country receives more. The rationing scale in Great Britain is taken as such a minimum basis. Five times as much land is needed to produce 1,000 calories of livestock products as of potatoes or bread; milk represents a more economical conversion from plant to animal products than meat does and should, therefore, have priority.

In supplying relief the production of the country concerned should be encouraged to the maximum extent and imports should supply the rest. Production of energy food must come first; in occupied Europe the actual production of crops has probably fallen by about 10 per cent, but that of livestock by 20–30 per cent. Relief should include a supply of agricultural machinery and fertilizers, so that production of potatoes, sugar beet and wheat or rye can be enhanced to the utmost; seed of suitable local varieties should be conserved for sowing. Crop production should have been restored to normal by the second harvest after liberation, but animal production will probably take eight years to re-establish fully, even if preference is given to female animals with artificial insemination from good bulls, and special veterinary care to raise health and fertility. Extra feeding stuffs should be provided by the offals from imported grains and, at a later stage, dairy cows might be imported from North America. Supplies of meat could be most rapidly increased by encouraging the rearing of pigs and poultry.

Of foods imported from abroad, cereals should come first where needed, and condensed and dried milks for mothers and children should have priority but there should also be early emphasis on meat and fats. If tropical oil seeds are imported whole, the residue could be used for feeding cattle. Meat, dehydrated to save shipping, should be imported for a considerable time to permit of livestock recovery.

The machinery to carry out the programme has been set up. The Allied Post-War Requirements Bureau in London has defined the requirements of each country, to be satisfied by the United Nations Relief and Rehabilitation Administration in co-operation with the Allied Military Government of Occupied Territory. The machinery for a longer-term policy was considered at Hot Springs. In Great Britain we have our part to play. Agriculture must, if anything, still further increase production, and we must anticipate a continuation for some time of rationing of anima products.

Miss Margaret Digby (Allied Post-war Requirements Bureau) stressed that the problem is one of applying limited resources to secure the maximum effect, but that we are more fortunate now than in 1920 because of the great progress in the organization of agriculture which has taken place both before and during the present War. The farmer now has confidence in the organization of agriculture, and managed production is thus made easier.

In liberated countries it will be necessary to change the machinery and type of rationing, which the enemy has imposed, to something more acceptable and to encourage production by a supply of desirable goods for which the foodstuffs produced can be exchanged rather than for a currency regarded with suspicion. The rise to higher nutritional levels will have to be gradual, and the feeding of people displaced and on the move will need special machinery Dr. P. L. Yates (Ministry of Economic Warfare mentioned that special inducements to farmers to produce might be offered on a points rationing system based on the amount produced. Production oversea must be further augmented. The surplus wheat would clearly now be insufficient, but it would be useless to offer surplus beans to people to whom beans are unfamiliar and unacceptable.

Nutritional Relief in the Field

The problem of the organization of nutritional relief in the field was discussed by Dr. Audrey Russell (Medical Director, International Commission for Wa Refugees). The problem is far beyond the scope of voluntary organization, but the experience gained by voluntary organization may be useful. Relief on the large scale should be through the ordinary channels of trade and the social services, and through whatever survives of the organization of local government It is through the social services, welfare centres and hospitals that opportunities for research may be found. Before any scheme can be started, a survey should be made of population, rations, local supplies markets and businesses, fuel, water supply, transpor and so forth, to be checked against official information. Bakehouses and bread constituents should receive special attention.

In Spain and France, the International Commission for War Refugees helped to supplement the rations of the static population by supplying weekly parcels of lentils, rice, sugar and tinned food to families in their own homes. They fed refugees on the road and in transit centres and semi-permanent camps and they provided extra milk and cereals for pregnant women and children and adolescents. For orphans and abandoned children, colonies were organized. Camps should not exceed 5,000 in number, and the ections should not include more than 1,000 each; each section should have an elected committee of 10, of whom one should sit on a central council. The ation cards for those receiving relief should register occupation as well as other details, so that appropriately trained persons can be summoned by loud-peaker to the vocation which is needed to help in he relief scheme; the people to be relieved are thus made as self-reliant as possible. In Catalonia, when he official ration in 1938 had fallen to 980 calories, he school-feeding scheme included provision of rest in the open for debilitated children while being taught at school. The children could thus live at home, so that it was not necessary to remove to a colony any but orphaned or abandoned children.

Prof. E. Nobel (formerly professor of children's diseases, University of Vienna) gave an account of the organization which was set up in May 1919, by Mr. Hoover on behalf of the U.S. Government, for feeding debilitated children in all lands. The freight charges were paid by the recipient countries. The ood was supplied cooked and was eaten on the spot. The children were selected according to bodily conition, regardless of race, creed or political opinion. Their bodily condition and nutritional needs were ssessed according to the Nem System of Prof. Pirquet.

Nutritional Research

Opportunities for nutritional research in the work of relief were indicated by Miss E. M. M. Hume (Lister Institute). The successful expedition to Vienna which Dr. Harriette Chick led for the Lister Institute and the Medical Research Council in 1919 roved that research in immediate post-war conditions can be made to yield valuable results; but this research should be only such as can be carried out nowhere else. The shape of post-war research will be the same now as then, but the tempo will have to be much quicker lest the research material is destroyed by relief; the first approach would be a scouting expedition.

At the end of the War of 1914–18 the Central Empires were completely ignorant of all the work on vitamins done in the English-speaking countries, so that ignorance reinforced the lack of food in promoting deficiency diseases. The first expedition to Vienna in 1919–20 was a reconnoitring expedition in which rickets, scurvy and adult rickets or hunger osteomalacia were investigated. The research was carried on throughout in close co-operation with the relief organizations, as should always be the case, and cases were found in hospitals, convents and sick benefit organizations. The relief missions were helped with advice.

Throughout the preliminary period an opening was being sought to make a planned crucial experiment in the occurrence of rickets in human infants. The opportunity was found at the University Kinderklinik, here Prof. Clemens von Pirquet had devised a system to suit famine conditions, by which infants were fed on a high proportion of carbohydrate and no vitamins. pproach was made to him through a distinguished neutral intermediary, Prof. Wenckebach, of Holland, and, with an extraordinary degree of international co-operation, Prof. Pirquet consented to allow this group of ex-enemy foreign women to carry out the experiment, which lasted from 1920 until 1922. The undertaking had the highest official backing from home, without which work in such conditions would at any time be impossible. Prof. Pirquet was inclined to believe that rickets was due to a low-grade infection but, when the contrary was proved, and rickets occurred and was then cured with cod liver oil, he acclaimed the result.

Although the investigation was so long drawn out, its shape was that of the preliminary reconnaissance in which alone observations or therapeutic trials could be made, followed by a planned experiment posing a special question and demanding the maintenance of negative controls. These main lines will remain the same to-day. Twenty years ago, the chief interest lay in the cure of florid deficiency states; to-day interest is greater in minor states of deficiency which may be utilized as criteria in assessing nutritional status, if their specificity can be established. This knowledge is especially needed for fixing the requirements of vitamins, to which there is a tendency at present to attach excessively high values. It should also be of the greatest help to those having the relief to do.

Whether the present War will offer any scope for the planned experiment, which demands the maintenance of negative controls, is uncertain. It is the possibility of legitimately obtaining negative controls for a human experiment which justifies the making of the experiment in such circumstances. There is not much likelihood that ignorance will provide the negative controls to-day, and it is to be hoped that insufficiency of relief will not do so either.

There are two rules which anyone trying to do such research should observe: to do only work which can be done nowhere else, and to remember that research workers are regarded as mainly a nuisance by the civil and military administrations.

Dr. A. P. Meiklejohn (Oxford Nutritional Survey) agreed that the first contact should be a reconnaissance, but a reconnaissance in force with mobile teams making rapid surveys of nutritional status by the various criteria nowadays recognized. Miss Hume disagreed with Dr. Meiklejohn as to the degree of reliability which can be attached to some of these criteria for assessing nutritional status; she believes that research should be directed to determining their reliability and specificity.

Summary

Lord Horder summed up the discussion. He admitted that it had not proved possible to keep the academic aspect of relief problems wholly distinct from the political. It was clear that the problem of supply could not be solved by mere transportation of surpluses. The problem is much deeper and more extensive than is commonly understood. Supply should be based on the minimum requirement as represented by current rations in the United Kingdom. He was of opinion that these should be reduced for some months in order to increase the supplies available for relief. The feeding of the Fighting Services might also be brought under review and some food thus released, and the extra protein ration for heavy workers might be cut for the same purpose. For research, new tools and new materials had been made available and, after the application of first aid, research should be there to help relief. AMGOT should be followed as quickly as possible by UNRRA, and hot on their heels should come "HUHO, Help Us to Help Ourselves".

COAGULATION OF COLLOIDS

By PROF. ERIC K. RIDEAL, M.B.E., F.R.S.

IN his presidential address delivered to the Chemistry Section of the Indian Science Congress last January, Prof. S. S. Joshi, of the Benares Hindu University, discussed *inter alia* various aspects of the kinetics of colloid systems.

In dealing with molecular reactions in solution, three methods of attack have yielded interesting and important results; one based upon gas kinetic concepts, the second on the Einstein diffusion equations and, finally, the transition state method of approach. In reactions between colloid particles or macromolecules, the second method of approach is generally employed and we are indebted to Smoluchowski for formulating the general principles.

The rates of coagulation are arbitrarily divided into rapid and slow rates respectively, the latter being derived from the former by the introduction of a factor ξ giving the fraction of collisions which are 'successful'. Since the rate of coagulation falls as particle charge rises, the potential barrier due to the diffuse layer of ions around the particles (the zeta potential ζ) can be regarded in the light of a potential barrier to be overcome for successful collision; we would thus anticipate that an equation of the type

$$\log \xi = \frac{K\zeta}{RT} + C$$

should connect the collision factor ξ with the zeta potential ζ. This is true for certain cases. We have found it to hold for quartz covered with gliadin, but in many cases the rate of coagulation is independent of ζ over a considerable range. Wiegner, Tuorila and Müller have shown that Smoluchowski's equations can be applied with considerable success to the problem of coagulation of uncharged particles, and extended the work to anisodimensional particles and more particularly to polydisperse systems. In the latter case it was shown that if the system were in motion the larger particles would 'strain out' the smaller ones. We might anticipate that the walls of the containing vessel would serve as collectors to neutral colloid particles undergoing auto-coagulation if the suspension was kept agitated. Prof. Joshi cites many cases of the effect of the containing vessel on the coagulation rates of sols, and makes the important observation that it is not necessary that the wall should have a zeta potential opposite in sign to that of the colloid.

Prof. Joshi rightly directs attention to the fact that the kinetics of coagulation do not obey the simple theory. The work of Levine in Great Britain and of the Amsterdam school of investigators has shown that for charged particles a position of minimum potential energy can be found in which the particles are a finite distance apart. We might thus expect to find doublets present in solution, which would require a definite energy of activation before they underwent true coagulation or coalescence; here the coagulation-rate would be pseudo-unimolecular. Another difficulty, which was first emphasized by Haber, is that the particles on coalescence undergo the phenomenon of 'ageing', resulting in a change of size and consequently a change in the diffusion coefficient on which the kinetics of coagulation are dependent. This ageing process, which can be followed in many cases by means of X-rays or by the rate of liberation of absorbed emanation or dyes, is virtually a process of recrystallization and proceeds mos rapidly in heteropolar systems such as colloida sodium chloride, and much more slowly in colloid such as the hydrous oxides or sulphides.

The most satisfactory method of determining th rate of coagulation of a colloidal solution is by direc observation with the aid of an ultra-microscope. Thi method is eminently suitable for colloidal system in which the refractive index of the disperse phas is markedly different from that of the dispersio medium; but where the light scattering is poor, a is the case for the proteins or hydrous oxides, man observational errors are apt to creep in. Man observers have consequently employed more indirec methods, especially the viscosity. The Benare school has made much use of refractivity measure ments for this purpose.

The utilization of viscosity measurements f following the rate of coagulation may be seriousl called in question. To a first approximation the vi cosity of a sol, if the electroviscous effect be eliminate by the addition of an electrolyte, should, in accor ance with Einstein's equation, be independent of th dispersity of the disperse phase, and only depend o its total volume. Prof. Joshi states that the viscositi of a number of dilute emulsions likewise obey tl Einstein equation. This can scarcely be the ca if the disperse phase has a measurable viscosity *per s* Prof. G. I. Taylor, some years ago, evaluated tl viscosity of a dilute emulsion in terms of the volun fractions and specific viscosities of the two phase but so far as I am aware, this equation has not bee subjected to any detailed experimental verificatio Changes in viscosity do, however, occur in coagulati of colloidal systems, partly because the speci volume of the disperse phase changes due to dehydr tion, partly because a shape factor begins to emer as the particles grow and, in some cases at leas as investigations on solutions of polymers have r vealed, the larger particles may be deformable und shear and thus raise the viscosity.

It is evident that many factors enter into t problem of the kinetics of coagulation and the determination, and we are indebted to Prof. Jos and his school at Benares for much painstaking a detailed work in this difficult experimental field. is satisfactory to note that real progress is bei made in that the factors operative are being isolat and identified.

ANGLO-PORTUGUESE SCIENTIF RELATIONS

By SIR GEORGE THOMSON, F.R.S.

IN view of the renewed intimacy which rece events have infused into the centuries-old associ tion of Portugal and Great Britain, and of the pro pect of increased co-operation between the tw countries, there is a special significance in t publication of a study in Portuguese by Prof. Amorim Ferreira on Anglo-Portuguese scienti relations*. The history of science is often treat as if it were a matter of a few great names, and o is apt not to realize the importance of the part play by those whose fame was greater in their life-ti than in after ages. In particular, problems of t transmission of ideas are often a matter of exploring the movements of the less well-known workers. This is a difficult and laborious task, but essential for an understanding of the spread of scientific knowledge and the birth of ideas by the cross-fertilization of two strains of thought. Prof. Ferreira has made a most successful and detailed essay on these lines, and one may hope that this book will inspire others to similar tasks.

---

* Relações científicas entre Portugal e a Grã-Bretanha. Por Amorim Ferreira. Pp. viii+76. (Lisbon: Academia das Ciências Lisboa, 1943.)

Without question, the greatest contribution of Portugal to science was the long series of voyages of exploration brought about by the enthusiasm and drive of Prince Henry the Navigator, who was himself a most successful example of collaboration between the two countries, for his mother was an English princess. His work broke down the scientific lethargy of the Middle Ages by making it clear that the known, even on this earth, is only a fraction of the knowable, which after all is the first condition for a vigorous school of science. But, even leaving his work aside, the relations between the countries have been extensive and varied.

Early in the list in chronological order we meet a series of Portuguese physicians who went to England in the sixteenth and seventeenth centuries, taking with them the benefits of Moorish medical science. Some of them held positions of great importance at the court and elsewhere and their experiences were sometimes more exciting than pleasant. For example, Rodrigo Lopez, who came to England in 1559, had dealings with Leicester and Essex, became chief physician to the Queen, and helped to influence her o the expedition of 1589. The failure of this and the ill-will of Essex led to his being unjustly accused of an attempt to poison the Queen in the interests of Philip of Spain. He was imprisoned, tortured and inally executed, a cruel reward for excellent work among the poor in the wards of St. Bartholomew's Hospital.

Lopez was a Jew, as were many of the Portuguese in England at this time; and later, even well into he latter half of the eighteenth century, their position in Portugal was insecure. Religious and other persecution has played a great part in the pread of scientific knowledge at many periods of the world's history, and our age has had ample experience of this example of good coming from evil. The movement between England and Portugal was not all in one direction, for a number of English Jesuits, mostly mathematicians, went to Portugal in the seventeenth century and promoted the study f their subject in that country.

The Portuguese physicians introduced the use of Peruvian bark to England, and developed a preparation of it long known as "English Water". One of the greatest of them, Castro Sarmento (1691–1762), improved this and broke with the secrecy common at the time by publishing his method of preparing it. It is interesting to note that through him the observations of the Jesuit astronomers at Pekin were transmitted to the Royal Society, an early example f inter-continental scientific relations.

During the latter two thirds of the eighteenth century the relations between Portugal and the Royal Society were very close. A great many papers of Portuguese origin were published in the *Transactions*, nd a surprisingly large number of Portuguese were elected fellows, some resident in England but others ot. Among the former one of the most remarkable was Bento de Moura, a man of great mechanical enius who improved Savery's steam engine in a way which earned the praise of John Smeaton. He afterwards returned to Portugal and entered the Government service, but fell foul of the then all-powerful Marquis de Pombal, and was imprisoned for five years in a fortress, where he died in 1766. Several of the correspondents of the Royal Society at this period were priests, among them Father da Serva, who helped to found the Academia Real das Ciências at Lisbon.

Towards the end of the eighteenth century, a number of students were sent from Portugal to England and Scotland to study medicine, a reversal of the tide in the previous century. Rather surprisingly, their director of studies at the Embassy was shocked at the expensive tastes of the Edinburgh students of the period.

In the nineteenth century a number of British scientific men did important work on the natural history of Portugal, and one, David Sharpe, is regarded there as the founder of Portuguese palæontology. In one case at least they received magnificent recognition, Alfred Tait being made Baron de Soutelinho for his work on phylloxera.

The contacts between Britain and the Portuguese islands have for long been especially close, and besides visiting scientific men, a number of British residents in Madeira have made valuable contributions to the natural history of the island. In another field of activity it is interesting to read that the artificial harbour of Ponta Delgrada was designed by Sir John Rennie.

The present book, which is dedicated jointly to the Academia das Ciências and the Royal Society, belongs to a series of scientific and historical works sponsored by the Academy.

PATULIN

In a recent article[1] we referred to the remarkable bacteriostatic properties of the fungal products which have been called 'penicillin' and 'helvolic acid'. Penicillin has recently been discussed at a meeting of the Royal Society of Medicine, which is reported in the *British Medical Journal*[2] and in the *Lancet*[3]. The *British Medical Journal* devotes an annotation to it entitled "Penicillin in Tunisia". Readers who wish to know the results of trials of penicillin in North Africa and the Middle East, and also the results of other clinical trials, should consult these two articles. Helvolic acid, isolated from *Aspergillus fumigatus*, var. *Helvola*, is the subject of an annotation in the *Lancet*[4]. It is distinct from 'fumigacin', which was isolated from *Aspergillus fumigatus* by S. A. Waksman, E. S. Horning and E. L. Spencer[5]. To these must now be added 'patulin', isolated from *Penicillium patulum*. The chemical properties and use of this for the treatment of the common cold are described in the *Lancet*[6].

In Part 1 of this article Prof. H. Raistrick explains that for some years he and his colleagues have been studying, at the London School of Hygiene and Tropical Medicine, the metabolic products of the lower fungi. A large number of these metabolic products have been isolated in a pure form, the chemical constitution of some of them has been determined and some of them have been synthesized. Prof. Raistrick and his co-workers have studied the anti-bacterial properties of some of these substances and give references in this article to their work. Patulin is one of these. Its chemical name is anhydro-

3-hydroxymethylene-tetrahydro-γ-pyrone-2-carboxylic acid.

In Part 2 of the article Dr. J. H. Birkinshaw, Mr. A. Bracken, Dr. S. E. Michael and Prof. H. Raistrick describe in considerable detail the biochemical and chemical properties of patulin. Pure patulin is a colourless substance which crystallizes in compact prisms or plates. It has been isolated from two strains of *P. patulum*, one obtained from Holland and one obtained from condenser water.

In Part 3 of the article Dr. W. E. Gye describes how he received a sample of patulin from Prof. Raistrick for chemotherapeutic tests on cancer. Being in the second stage of a common cold, Dr. Gye douched his nasal passages with a watery solution of patulin. Within an hour his nasal passages were cleared; the douches were repeated twice with weaker solutions; a night of undisturbed sleep followed and next morning he was quite well and back at work. A later trial failed to cure the early stages of another cold, and Dr. Gye suggests that patulin may not act on the virus stage; the secondary stage of infection with Gram-positive and Gram-negative organisms was, however, completely prevented. Later he found that solutions of 1 : 20,000 of patulin were painless (the earlier solutions of at least 1 : 1,000 tried by Gye caused some pain) and colleagues and friends of Dr. Gye's tried these. One of them reported that patulin did not reduce the temperature nor shorten the duration of influenza; but it did prevent the nasal symptoms which often obscure the diagnosis of this disease. Only one of these volunteers reported no effect at all. The results obtained by the others suggested that trials under controlled conditions were warranted.

Part 4 of the article describes these trials, which were conducted on Naval personnel by Surgeon Commander W. A. Hopkins. Experimental work showed that patulin has bacteriostatic powers against a number of Gram-positive and Gram-negative aerobic organisms. Preliminary experiments have shown that it is also active against anaerobes. Commander Hopkins says that patulin differs from penicillin, gramicidin and citrinin in showing no selective differentiation between Gram-positive and Gram-negative organisms. It is very much less active than penicillin against Gram-positive organisms, but is more active than penicillin against Gram-negative ones. It is more active than penicillin against organisms of the coli-typhoid-salmonella group and against *Bact. dysenteriæ* Shiga. The *Lancet*, in its leading article entitled "Moulds and Colds"[7], points out that these comparisons are made against the impure preparations of penicillin available two years ago. Pus and serum do not affect its action. Solutions of 1 : 8,000 do not affect the phagocytic activity of leucocytes, although solutions of 1 : 2,000 inhibit it.

Patulin keeps well in a phosphate buffer at *p*H 6 and this was used for the trials. Patients in whom differential diagnosis between the common cold and influenza arose were excluded; only cases of acute or subacute rhinitis with or without pharyngitis, that is, cases of the ordinary common cold, were used. The commonest organisms found by swabbing the nasopharynx of the patients were *Strep. pneumoniæ*, *Micrococcus catarrhalis* and streptococci (alpha and beta). When solutions of patulin of from 1 : 5,000 to 1 : 20,000 were sprayed at intervals of four hours or so into the nose, or snuffed up from the hand or introduced by a pipette or gargled, 57 per cent of the patients recovered completely within forty-eight hours, while only 9·4 per cent o the controls recovered in this time. A large number were cured by the end of twenty-four hours. When five cases of influenza were treated with a 1 : 10,000 solution, the course of the disease was not influenced in any way. This confirms Gye's statement above. Some difficulty was experienced in assessing the results, because the common cold has few objective signs and the patient's statements are not always reliable. A statistical note on the results by Prof. Major Greenwood concludes the whole paper.

Commander Hopkins is wisely cautious about the conclusions to be drawn from his results. He says that the etiology of the common cold is not yet fully understood and that further extended trials are required before definite claims can be made for patulin. It would seem that extended trials on patients with pre-existing or concomitant sinusitis are especially needed, because, in some cases described by Commander Hopkins, after an apparent cure of a cold by patulin, severe sinusitis developed. The public interest in a cure for the common cold is naturally so keen that Commander Hopkins's caution is as necessary as the statement by Prof. Raistrick that patulin will not be released for general issue until further large-scale confirmatory trials have established its value and complete freedom from danger. Meanwhile the Therapeutic Research Corporation, which has helped both financially and technically in the work here described, is arranging for the manufacture of patulin in adequate quantities.

OBITUARIES

Mr. E. H. Clifford

EDWARD HERBERT CLIFFORD, who died on Octobe 11, aged sixty-seven, was a distinguished mining engineer whose name will long be remembered by hi professional brethren. His career contained no spectacular incident to bring his name prominently before the general public, his *métier* being rather tha of a 'back-room' boy, who nevertheless left behind him a record of solid achievement which will remain a monument to his name so long as gold and copper mining is carried on in the Transvaal and the Rhodesias.

Born in 1876, he went to St. Paul's School and commenced his technical education in 1892 unde Sir Clement Le Neve Foster. Graduating as an associate of the Royal School of Mines in 1895, h spent a year at the Bergakademie, Freiberg, before going to South Africa. During his early years on the Witwatersrand he filled a number of junior post of a varied nature both on the surface and underground in different mines, thereby laying the foundation of the wide general knowledge he ultimately accumulated. In 1899 he obtained his first executiv appointment as chief surveyor at Langlaagte Deep which now forms part of the Crown Mines. During the South African War he enlisted in the Johannesburg Mounted Rifles and saw extensive active service in the Eastern Transvaal. On demobilization h returned to Langlaagte for a short time before being appointed chief surveyor to Rand Mines, Ltd. During 1907–11 he acted as assistant to the consultant engineer to the Eckstein Group and was given the highly responsible task of investigating and reporting on properties in various localities which were then considered 'outside' areas but are now recognized as extensions of the original Rand series. One of these was the Modder B Mine, of which he was appointed manager in September 1911 just as it came into production. The company paid its initial dividend the following year and has continued to pay annual dividends ever since. Modder B, at the time Mr. Clifford became manager, differed in many respects from the then operating mines of the Central Rand in that the gold-bearing conglomerate had a very flat angle of dip. Consequently methods of working and development differing materially from those in common use on the goldfield had to be devised. The record of the mine is an eloquent testimony to the skill and knowledge with which Mr. Clifford faced and successfully overcame the problems. . .

Clifford's technical ability was so widely recognized and his professional status so well established that in 1912 he was appointed consulting engineer in Johannesburg to the Central Mining and Investment Corporation, a position he held until 1923, with the exception of a period during the War of 1914–18, when he acted as chief technical adviser to the Mineral Resources Department of the Ministry of Munitions. While with the Central Mining Group he became nterested in the question of deep mining, which he foresaw would become a matter of vital importance to the Witwatersrand. He gave much time and thought to the problems of deep winding and ventilation which would thus arise and pressed his views strongly on his colleagues in regard to these matters.

His experience with the Ministry of Munitions in he War of 1914–18 was invaluable to Sir William Larke and his colleagues on the Non-Ferrous Metallic Ores Committee, which was formed in 1940 to advise he Minister of Supply on the possibility of supplies from home metal mines during the War. Nobody knew better than Mr. Clifford that ample labour, time, money and patience are required to open or re-open even the smallest mine, and that, unless steps were taken quickly, nothing of any value was likely o be produced in the immediate future. He also had strong views on the necessity for reviving home metal mining on a long-term basis, and at times expressed himself forcibly on the subject.

In 1919 he returned to South Africa for a few years and, after resigning his position with the Central Mining Corporation, spent some time visiting mines in various parts of the world.

In 1926 he was appointed consulting mining engineer to the British South Africa Company, and commenced what was probably the most productive part of his professional life. Though he held no post directly responsible for the development of the great Rhodesian Copper Mines, he visited Rhodesia on behalf of the chartered company every year, where his advice was eagerly sought by the local managements, and his informed reports of great value to his colleagues in London.

Mr. Clifford's eminence as a mining engineer was recognized by the members of his profession when he was elected president of the Institution of Mining and Metallurgy in 1941, a difficult task in a difficult time, which he carried out admirably. His devotion to the Royal School of Mines was proverbial and, however busy he might be, he was always ready to advise and assist young mining engineers. He went to great trouble to find ways and means of encouraging the right type of recruit to enter the profession. He was also a governor of the Imperial College of Science and Technology, being appointed as their representative by the Royal Commissioners for the Exhibition of 1851.

Yachting was his great hobby, and, whenever his many professional duties allowed him, he turned to the *Vigilant* for recreation. She was a Thames barge converted into a comfortable cruising yacht in which, assisted by his wife, formerly Miss Jane Leck of Johannesburg, he delighted to entertain his friends. Every year he attended the barge races, flying the winning pennant won by *Vigilant* many years ago. Many of the fitments he made himself, as he was both a skilled carpenter and metal worker.

J. A. S. RITSON.

WE regret to announce the following deaths:

Mr. Clive Cuthbertson, O.B.E., F.R.S., fellow of University College, London, on November 16, aged seventy-nine.

Sir Edward Poulton, F.R.S., formerly Hope professor of zoology in the University of Oxford, on November 20, aged eighty-seven.

NEWS and VIEWS

Economic and Technical Reconstruction in Europe

THE address on "Economic and Technical Reconstruction in Central Europe" delivered by F. Nemec, Minister of the Czechoslovak Government in London, at a meeting of the Association of Austrian Engineers, Chemists and Scientific Workers on July 12 not only pays a tribute to the work of the Inter-Allied Committee on post-war requirements. It also gives an outline of the plan which that Committee has already worked out to cover the requirements for the first ix months after the liberation of Europe. The Committee indeed forms an important and valuable basis for setting up the proposed United Nations Requirements and Rehabilitation Association. Mr. Nemec mphasized once more that the technique of executing and rendering speedy relief to the enemy-occupied territories leads naturally to the second task of economic rehabilitation, which is essential if the European nations and European civilization are to be saved.

The requirements of the 'master plan', Mr. Nemec indicated, are based, so far as foodstuffs are concerned, on British consumption, giving due consideration to variations in climate and to any unusually severe malnutrition as well as to differences in the general diet of the countries concerned. Animal and vegetable oils and fats are of particular importance, and a maximum consumption of 70 per cent of the prewar consumption has been accepted for the first six post-war months, for countries like Britain where the consumption is high, and smaller restrictions for countries with a normally lower consumption. The importance of a quick supply of fertilizers as an essential to a recovery of agriculture was stressed, and Mr. Nemec uttered a warning with regard to the timber and paper position. Requirements in respect of leather, skins and boots over the same six-month period have been calculated on the consumption under the British rationing scheme of 1941–42, and the British ration also forms the agreed basis in respect of imports of textiles. Careful attention has also been given in the plan to the consumption of crude oil and its by-products and of coal. Czechoslovakia expects to be once more in a position to export coal, of which Austria was formerly her best customer. Requirements of the non-ferrous metals, copper, lead and zinc will be great, and supplies of medicants, seeds, certain machinery such as locomotives and lorries, will be of primary importance.

Mr. Nemec said that the joint organization of the United Nations will operate on the basis of a pooling of all means of transport and unified management of the entire post-war European transport system for relief purposes. One of the basic assumptions of the Leith Ross Committee was that the aim must be the full employment of the nations concerned. Mr. Nemec referred briefly to the problems involved in the industrialization of South-Eastern Europe, in which Czechoslovakia might well help; and expressed the view that it is essential to organize import control of important raw materials now, by creating pools for the supply of essential kinds of goods for the post-war relief period and afterwards.

Twenty-One Years of Broadcasting

NOVEMBER 1943 sees the completion of twenty-one years of regular and authorized broadcasting in Great Britain, and the coming-of-age of the British Broadcasting Corporation—formerly a limited company with the same initial letters, the British Broadcasting Company, Ltd. The occasion was celebrated by a special programme on Sunday, November 14, during which Mr. John Snagge presented a series of B.B.C. reminiscences. On the following Wednesday, November 17, Mr. Stuart Hibberd, chief announcer of the B.B.C., read a paper before the Royal Society of Arts entitled "The Coming-of-Age of Broadcasting". The amazing developments which have been achieved during the growth of broadcasting in Great Britain have been due to the excellent team-work of everybody concerned—artists, programme organizers and engineers alike.

Mr. Hibberd stated that it was the general strike of 1926 which brought home to people the importance of broadcasting in a national emergency, and demonstrated the power of the spoken word. The technical achievements following that include the introduction of the Empire short-wave service in 1927, the broadcasting of the bells of Bethlehem in the Christmas programme of 1933, and of a programme by members of the Byrd Antarctic Expedition from their camp nearly 9,000 miles away in April 1934. These programmes record the attainment of successful collaboration with other organizations such as the Columbia Broadcasting System of America, while one of the greatest triumphs of the outside broadcasting organization was that of the coronation of King George VI, when the whole programme was maintained for six hours non-stop without using a studio at all. During the War, the European and overseas broadcasting services have been developed to the point at which day and night transmissions are no made almost continuously in no less than forty-fiv foreign languages. In his closing remarks, Mr Hibberd directed attention to the possibilities of th future; and among these was a plea for a post-wa university of the air, by means of which student could be placed in touch with the greatest authoritie on their subjects in the land.

Indian Association for the Cultivation of Scienc

THE annual report of the Indian Association fo the Cultivation of Science for the year 1942 include the presidential address of Sir U. N. Brahmachari the report of the Committee of Management and list of papers appearing during the year in the si issues of the *Indian Journal of Physics* and *Proceeding of the Indian Association for the Cultivation of Science* Sir U. N. Brahmachari, referring to the beginnings o the Association, quotes from the sketch of the origina scheme given by Mahendra Lal Sircar on December 1 1875, indicating that the founder had in mind a institution combining the scope, character and objec of the Royal Institution in London and the Britis Association for the Advancement of Science. D Sircar hoped to see it develop into an institutio where his countrymen, after finishing their universit education, would on their own account carry ou original research in the different branches of science When the scheme had reached maturity, anothe scheme for a technical institution was launched b the Indian League, and it was only after some controversy that a decision was reached not to amalgamate the schemes, and the Association was inaugurated on July 29, 1876.

Sir U. N. Brahmachari then discusses the future o the Indian Association, and refers to the proposal t create a new body of members to be called 'fellows in recognition of distinguished research work conducted by them. The number of life-members ha increased by 17 since 1942 and of ordinary member by 60. It was proposed to remove the Institute to place nearer a seat of scientific learning, to renovat the chemical laboratory and create a fellowship, an ultimately a professorship, in the name of Sir P. Ray. The Department of Chemistry proposes to tak up the study of some of the more important problem in industrial chemistry, and an approach to th Governments of India and Bengal, the Board Scientific and Industrial Research and the Rockefell Foundation might be desirable. In addition t research, however, it is proposed to undertake th propagation of science, for example, by means of series of lectures by men of the eminence of Sir J. Bose, Sir C. V. Raman, Dr. F. W. Aston and other as well as to continue the present arrangements f research by postgraduate students for the doctorat of various universities. The president also suggeste regular meetings for the discussion of scientific subjects by the research workers of the Association, an full co-operation with the University College Science, Calcutta, the Bose Institute and the scien departments of the Colleges affiliated to the Universit of Calcutta, as well as the Calcutta School of Tropic Medicine and the All India Institute of Hygiene.

Absenteeism among Women

EMERGENCY REPORT No. 4 of the Industrial Healt Research Board (H.M. Stationery Office, 1943. 2*d* gives a study of absenteeism among women for th period 1942. It is concerned with the amount an distribution of absenteeism among women rath than with the causes. Random samples of workers in factories were studied for periods of six weeks, at times of the year which were not affected by leave or annual holidays. The women worked on the three-shift system and the shifts were changed weekly. Analysis of the figures showed that, contrary to the general view, few women habitually lost one or more shifts each week, but a large majority were absent for varying lengths of time at irregular intervals. This suggests a study of the personal causes of absenteeism. Much of the absence was due to full-week absence and this was mainly due to sickness. Married women lost more time than single women, and they also tended to have more longer and fewer shorter absences than single women. Absenteeism was highest on Saturday, and was lowest on pay-day. A factory that employed a very large number of women, and which had grown very rapidly and was situated in an isolated position, had a higher absence rate than one of more stable development and more advantageously placed. On the average it was found that there was little difference in absenteeism between women who took up to one hour to reach the factory, but above that limit absenteeism increased with travelling time.

Bicentenary of Martin H. Klaproth (1743-1817)

BORN on December 1, 1743, a few months after Lavoisier, Martin Heinrich Klaproth was the foremost chemist in Germany, and it was largely due to him that his fellow-workers in Berlin adopted the new theories of the French chemists in place of the phlogiston theory of their countryman Stahl. Klaproth was born in the small town of Wernigerode, in Upper Saxony. He was educated first for the Church. He began his life's work as an assistant in a laboratory at Quedlinburg, where he spent seven years. After short periods passed in Hanover and Dantzig, he entered the service at Berlin of the elder Valentin Rose (1736–71), the grandfather of the well-known chemists, Heinrich and Gustav Rose. His employer's early death in 1771 led him to set up a laboratory of his own and he afterwards gained a high reputation for his numerous and accurate analyses of minerals. His researches were regarded as a pattern for the rising generation of chemists, and to him we owe much of the early known facts about zirconium, uranium, tellurium, cerium, titanium and beryllium. He also prepared a mineralogical system, and with Friedrich Benjamin Wolf published the first German chemical dictionary. He held various public appointments; in 1788 he was elected a member of the Berlin Academy of Sciences, and when the University of Berlin was founded in 1809 by Wilhelm Baron von Humboldt, Klaproth was given the chair of chemistry. As a member of the Academy, he had in 1792 repeated the most important experiments of Lavoisier, and it was this that contributed to the spread of the new theories. He kept active to the last and died in Berlin on January 1, 1817, at the age of seventy-three. His son, Heinrich Julius von Klaproth 1783–1835), was a distinguished Orientalist and raveller.

Science Class Lecture Cine-Films

A VERY successful film exhibiting the Brownian movement has recently been made in the Natural Philosophy Laboratory of the Royal Technical College, Glasgow, by Mr. Thomas S. Wylie, a former student of the College, in collaboration with Dr. Quintin Moore, of the Bacteriology Department. A dilute aqueous suspension of colloidal silver particles of order $50\ \mathrm{m}\mu$ (50×10^{-7} cm.) diameter was viewed with the aid of a 'Cardioid' ultra-microscopic condenser in conjunction with a microscopic combination magnifying about 1,200 times. The film was photographed through the eyepiece of the microscope. This is an excellent example of a really useful application of cine-photography to the experimental illustration of a science class lecture. In order that the students of a large class can observe individually the Brownian movement under the microscope, it is necessary to have the apparatus set up on many successive meetings of the class. With this film the whole class can observe the motions in a matter of three or four minutes. Mr. Wylie has also made an interesting film which, in a time of about ten minutes, shows the following surface tension experiments, some of which are difficult to set up and manipulate: (*a*) formation of a drop with the subsequent Plateau's spherule; (*b*) camphor movements on a clean water surface; (*c*) the beating 'mercury heart'; and (*d*) the difference in pressure in large and small bubbles.

Do All Statements Make Predictions?

IN the July issue of *Mind*, Mr. John Wisdom, under the title of "Other Minds (VII)", continues his lengthy philosophical dialogue dealing with our knowledge of other minds. In this episode his three interlocutors, Black, White and Gray, expound in that strange, obscure, slang-ridden, ungrammatical English which Mr. Wisdom affects, a theme which merits the attention of all interested in the problems of epistemology. The theme is simple: "what makes a statement objective also makes it predictive". It would be impossible in a few words to review the subtle analysis, the fine distinctions, which emerge from Mr. Wisdom's variations on this theme. Every kind of statement which might claim merely to report present fact and not to predict anything is brought to the bar and convicted of lurking predictiveness. The knowledge expressed in the statement "I am in pain" is finally admitted to be not predictive, but it is alleged to be a queer kind of knowledge because we cannot conceive what it would be to be wrong on such a matter. Again, speaking of statements such as "All men are mortal" the author says: "They become more really knowable, more necessarily true, the fewer future facts can make them fail, and they become quite knowable and quite necessarily true only when no future fact can make them fail". This is what America's greatest philosopher, Charles Sanders Peirce, said forty years ago. It has not ceased to be true, and Mr. Wisdom embroiders its expression with many illuminating subtleties of thought.

Some Old Letters of Astronomical Interest

IN an article entitled "An Eighteenth Century Correspondence" in the October issue of the *Observatory* (65, 92; 1943), Prof. H. C. Plummer reports on the contents of a collection of old letters received by Nathaniel Pigott and lately presented to the Royal Astronomical Society. Nathaniel (*c.* 1740–1804) was the father of Edward Pigott, who discovered the variability of η Aquilæ. He was himself greatly interested in astronomy, making observations of a partial eclipse of the sun in 1765 and of the transit of Venus in 1769. He was elected a fellow of the Royal Society in 1772, and spent five months in the Low Countries in survey work. Five years later he made his home at Frampton, Glamorgan, where he equipped a private observatory with a transit instrument by Sisson, a 6-ft. achromatic telescope by Dollond, and other instruments. He lived in the heyday of the professional instrument maker, and such men as Bird, Peter Dollond and Sisson figure among his correspondents in this collection. Distinguished members of the Paris Academy of Sciences, of which he was elected a corresponding member in 1776, also corresponded with him, and the collection includes letters from Lacaille, Messier, Le Monnier and others. Among English astronomers whose letters to Pigott are preserved, Maskelyne and Hornsby are perhaps best known. At present, of course, the question of printing the collection cannot be contemplated; but the Royal Astronomical Society intends to preserve the correspondence carefully until such time as a selection, at least, of the letters can be published.

Earthquakes Recorded during July and August

BETWEEN July 4 and 31 inclusive thirteen strong earthquakes were registered at Kew, the strongest being apparently on July 29. This came from an epicentre 6,770 km. distant bearing an azimuth 270° from Kew, and attaining at Kew an amplitude of 870 μ. Other strong shocks were on July 11, registered at 02h. 30m. 14s. U.T. with maximum amplitude 45 μ from 17,700 km., and on July 23 registered at 15h. 07m. 28s. U.T. with maximum amplitude 87 μ from 12,200 km. At Wellington, New Zealand, earthquakes registered on July 11 at *ca.* 02h. 12m. 37s. from an epicentre at lat. 33° S. long. 177° W., and on July 23 at 15h. 03m. 45s. from an epicentre distant *ca.* 66°. During July in New Zealand there were nine locally felt earthquakes, the greatest being on July 10 in upper Takaka with Mercalli scale strength IV, on July 23 at Masterton with Mercalli scale strength III, and on July 28 from Christchurch to Timaru with Mercalli scale strength III.

In August there were five strong earthquakes recorded at Kew and twenty at Toledo. Those in common were August 2, Kew 01h. 06m. 39s., Toledo 01h. 06m. 38s., distance from Kew 19,000 km. and from Toledo 19,300 km.; August 10, Kew 15h. 24m. 48s., distance 8,100 km.; Aug. 12, Kew 05h. 03m. 14s., Toledo 05h. 04m. 06s., distance from Kew 9,300 km. and from Toledo 11,180 km.; and August 13, Kew 07h. 47m. 05s., Toledo 07h. 45m. 29s., distance from Kew 6,200 km. and from Toledo 5,100 km. The United States Coast and Geodetic Survey has determined the epicentre of an earthquake on August 31, this being lat. 13½° N. long. 91½° W., which is in the Pacific Ocean just off the south-west coast of Guatemala in Central America. Time at origin was 16h. 10·5m.

The Night Sky in December

FULL moon occurs on Dec. 11d. 16h. 24m. U.T., and new moon on Dec. 27d. 15h. 23m. The following conjunctions with the moon take place: Dec. 11d. 00h., Mars 7° N.; Dec. 12d. 01h., Saturn 2° N.; Dec. 17d. 07h., Jupiter 0·8° S.; Dec. 23d. 19h., Venus 3° S.; Dec. 18d. 13h., Mercury 2° S. The following occultations of stars brighter than magnitude 6 take place: Dec. 4d. 18h. 09·5m., ψ Aqr. (*D*); Dec. 13d. 00h. 51·4m., ν Gem. (*D*); Dec. 13d. 02h 05·3m., ν Gem. (*R*); Dec. 24d. 06h. 19·2m., γ Lib (*D*). The times refer to Greenwich and *D* and *R* refer to disappearance and reappearance respectively Mercury sets 20 minutes after the sun at the beginning of the month, and about an hour later than the sun in the middle of the month. It attains its greatest easterly elongation on Dec. 23 and on Dec. 30 i stationary. At the end of the month Mercury sets a 17h. 15m. Venus, a morning star, rises at 3h. 22m. 3h. 53m. and 4h. 34m. at the beginning, middle and end of the month respectively. Mars, in the constellation of Taurus, can be seen through most o the night, rising early in the evening and setting in the morning at 8h. 36m., 7h. 11m. and 5h. 49m. at the beginning, middle and end of the month The planet is in opposition on Dec. 5. Jupiter, in the constellation of Leo, can be seen late at night, rising at 22h. 11m., 21h. 17m., and 20h. 12m. at the beginning, middle and end of the month respectively Saturn is near Mars but sets later in the morning In addition to the above phenomena, Jupiter will be occulted by the moon on Dec. 17d. 07h. 18·6m., reappearing at 8h. 14·9m.. Winter solstice commences on Dec. 22d. 17h. The Geminid meteors are active during Dec. 1–12, emanating from different radiants in the constellation of Geminus.

Announcements

LIEUT.-COLONEL EDGAR PAM, consulting engineer to, and deputy delegate director of, the Mond Nicke Company, Ltd., has been elected president of the Institution of Mining and Metallurgy for the session 1944–45.

THE Institution of Mechanical Engineers announces that, thanks to arrangements made by the War Organisation of the British Red Cross and the Order of St. John of Jerusalem, 37 candidates recently sat for the Institution's examinations in prisoner of-war camps in Germany. No fewer than 3 (92 per cent) passed with an exceptionally high average percentage marking. The results reflect credit both on the candidates and on members o the Institution and others in the camps who organized classes and acted as instructors.

THE following appointments have been made in the Colonial Service: D. J. Cowan to be agricultura officer, Uganda; A. Storrar to be agricultural officer Kenya; T. P. Weldon to be agricultural officer Sierra Leone; M. J. Fitzpatrick to be veterinary research officer, Kenya; G. Q. Fowler to be veterinary officer, Nyasaland; P. D. L. Guilbride to be veterinary officer, Northern Rhodesia; G. W. G. Briggs (agricultural officer, Nigeria) to be senior agricultura officer, Nigeria; J. W. Wallace (agricultural officer Nigeria) to be senior agricultural officer, Nigeria F. S. Collier (senior assistant conservator of forests Nigeria) to be conservator of forests, Nigeria.

DR. J. D. ROLLESTON writes: Dr. John Fulton has directed my attention to an error in my obituary of Dr. A. C. Klebs in NATURE of September 4, p. 269 The bibliography of Harvey Cushing was prepared by the Harvey Cushing Society, not by Klebs. Dr Fulton was the compiler, but the work was principally done by Louise Eisenhardt and Miss Madeline Stanton, Dr. Cushing's former secretary.

Molecular Weight of Native Cellulose

THE molecular weight of cellulose is of great interest to cellulose chemistry, and many attempts have been made to determine it. The cellulose derivatives, esters and ethers, can in general be dissolved in simple organic solvents, and their molecular weights determined by the osmotic pressure method. It is questionable, however, if the derivatives can be prepared without degradation of the cellulose molecule. Therefore the study of cellulose in cuprammonium solutions is of very great interest. It has never been possible to carry out osmotic measurements of these solutions, owing to their high vapour pressure and the difficulties of membrane materials. Staudinger[1] has extrapolated his 'viscosity rule' from measurements of relatively low molecular weight materials and obtained degrees of polymerization of 2,000–3,000 for native cotton and ramie. Sedimentation equilibrium measurements were performed by Kraemer[2], who obtained values up to 1,300 for purified cotton linters, and estimated the molecular weight of native cellulose to be at least 570,000 (D.P. 3,500). Later, Mosimann[3] showed that sedimentation equilibrium experiments with filament molecules (nitrocelluloses) of very high molecular weights give doubtful results owing to swelling-pressure effects.

We have measured the sedimentation and diffusion velocities of different celluloses in cuprammonium solution. The complexity of the solution and the thread-like shape of the cellulose molecules make the measurements difficult. In order to achieve reliable results it is necessary to extrapolate sedimentation and diffusion measurements to zero concentration of cellulose. Both sedimentation and diffusion of these highly asymmetrical molecules are strongly affected by concentration. On dilution, the sedimentation velocity increases and the diffusion velocity decreases. The sedimentation velocity at free sedimentation (zero concentration) may be graphically extrapolated. By experience it has been found that the concentration function obeys approximately the formula

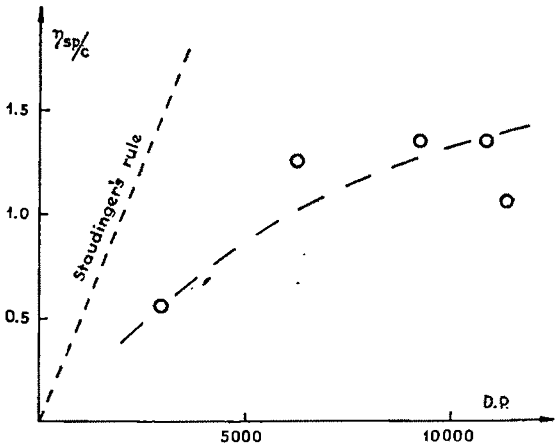
$$s = \frac{s_0}{1 + kc},$$

where s is the sedimentation constant determined at the concentration c, k is a constant and s_0 is the sedimentation constant at complete dilution. The diffusion constant at zero concentration may be determined from a single experiment by using the Boltzmann equation[4]. The diffusion constant has been found to be almost linearly dependent on concentration.

For calculation of molecular weights the formula

$$M = \frac{RTs}{D(1 - V\rho)}$$

(Svedberg[5]) has been used. This formula is independent of the shape of the molecules. The partial specific volume V of cellulose in cuprammonium solution was determined by Stamm[6] to be 0·642. Refractive index measurements have made it very probable that one copper atom is bound to every glucose unit. The cellulose copper complex has a lower specific volume than pure cellulose, and by taking the copper ion radius into consideration it was calculated to be 0·485.



All experiments were performed in a purified nitrogen atmosphere, and special arrangements were made for complete exclusion of air when filling centrifuge and diffusion cells. The results for different celluloses are given in the accompanying table.

Cellulose	$s_{c=0}$	$D_{c=0}$	M (cellulose)	*D.P.*
Unbleached cotton linters	10·7	0·23	$1\cdot50 \times 10^6$	9,200
Raw Georgia cotton	10·4	0·33	1·00	6,200
Nettle fibre cellulose	13·7	0·25	1·76	10,800
Ramie	10·3	0·18	1·84	11,300
Sulphite wood pulp	6·2	0·43	0·46	2,900

The sedimentation constants are given in Svedberg units (10^{-13} cm./sec. dyne), the diffusion constants in units of 10^{-7} cm.^{2}/sec.

It will be noticed that the molecular weights reported here are appreciably higher than those earlier reported for cellulose. For comparison, viscosity measurements were made. The results are given in the accompanying diagram. From this it is obvious that our results do not correspond to Staudinger's hypothesis of a linear relation between relative viscosity and molecular weight. At least for these giant molecules, the molecular weight increases very much faster than viscosity. From the sedimentation data it can also be deduced that the longer the molecules are, the more do they tend to become curled.

The free native celluloses in seed hairs and bast fibres have larger molecules than the prepared wood pulp. If wood is treated directly with cuprammonium, some of the cellulose goes into solution, and its sedimentation constant is about 8, suggesting a *D.P.* about 5,000.

The investigations are in progress, and full details will be published elsewhere. Financial support has been received from the Royal Swedish Institute for Engineering Research, the Rockefeller Foundation and the Wallenberg Foundation.

Decomposition of Hydrogen Peroxide by Catalase

WE have postulated previously that the catalytic decomposition by catalase of hydrogen peroxide to molecular oxygen and water is accompanied by changes in the valency of catalase iron[1]. This supposition is strongly supported by spectroscopic and manometric experiments carried out on azide-catalase. As additional evidence in support of this view, we brought forward the results of experiments carried out in Barcroft differential manometers, showing that under certain conditions even the activity of free catalase is inhibited when oxygen is completely removed from the surrounding medium and replaced by pure nitrogen. Our manometric experiments were repeated by Weiss and Weil-Malherbe[2] who, using Warburg manometers, failed to obtain this inhibition. Johnson and van Schouvenburg[3] also failed to confirm our results using luminescent bacteria as indicators of decomposition of hydrogen peroxide by catalase in complete absence of oxygen. However, we repeated our experiments from time to time, using different enzyme preparations, and invariably confirmed our previous results. The failure by other workers to obtain similar inhibition was explained by us[4,5] as being due probably either to some difficulty in complete elimination of oxygen from Warburg manometers or to some defects in their enzyme preparations.

However, two considerations induced us to reinvestigate the whole problem: (1) the ease with which our experiments were confirmed in our laboratory by Dr. H. Laser, who used for this purpose ordinary Warburg manometers; and (2) a private communication from Dr. Dickens informing us that he was completely satisfied with the experiments by Weiss and Weil-Malherbe carried out in his laboratory.

After a careful analysis of every step of our manipulation, special attention was paid to the nitrogen used in our experiments, with the view of detecting in it some impurities which could be responsible for the effects we invariably obtained.

The nitrogen in our experiments was purified by passage through a combustion tube filled with wire-form copper oxide reduced *in situ* with hydrogen and heated to redness in an electric furnace. The view that our purified nitrogen contained traces of impurities such as oxides of nitrogen was confirmed in various ways which can be summarized as follows:

(1) Incubation of a very dilute enzyme preparation with nitrogen purified as shown above, followed by evacuation and refilling the Barcroft manometers with air before mixing the enzyme with peroxide, already had a strong inhibitory effect upon the enzyme.

(2) The nitrogen from the furnace bubbled through sulphanilic acid – α-naphthylamine reagent at the rate of 100 ml. per minute for 20 minutes, together with a stream of oxygen, gave a positive colour reaction corresponding to 2 μgm. sodium nitrite.

(3) We have shown previously[6] that catalase combines with nitric oxide forming a well-defined compound.

(4) Decomposition of hydrogen peroxide in air by catalase is strongly inhibited by sodium nitrite in a concentration about ten times higher than those which could be detected in our experimental flasks, assuming that, in these flasks, 100 ml. of nitrogen comes into contact with our dilute enzyme preparations. On the other hand, the diazo reaction may be incomplete under these conditions.

(5) At the conclusion of all experiments in which inhibition was obtained, the liquid in the flask gave a positive brucine test for $-NO_3$.

(6) Passing the purified nitrogen to the manometers via a charcoal trap completely abolished the inhibitory effect of nitrogen.

(7) On lowering the temperature of the furnace so that within the combustion tube it reached only 400° C. and near the outlet somewhat lower, the inhibitory effect due to nitrogen together with the reaction for the oxides of nitrogen were completely abolished.

These experiments clearly demonstrate that the inhibition of catalase activity ascribed previously to the absence of oxygen was due to traces of some oxides of nitrogen formed during the purification of nitrogen owing to the high temperature of the furnace. It is interesting to note that out of many enzymes tested with this 'purified' nitrogen, so far only catalase, perhaps on account of high dilutions, seems to be affected by such minute traces of impurities. These results, as will be shown separately, do not invalidate our view that the catalytic decomposition of hydrogen peroxide by catalase is accompanied by reversible changes in the valency of its iron; a view shared by several other workers[7,8,9]. They only show that conditions have not yet been found for the detection of the ferrous state of free catalase during its activity owing to its much too rapid re-oxidation.

Mechanism of the Butanol-Acetone Fermentation

THE mechanism of sugar breakdown in alcoholic fermentation by yeast, lactic acid fermentation by lactic acid bacteria and glycolysis by animal tissue has been elucidated, but the intermediate steps of the butanol-acetone fermentation are not yet known. The main problem, the transformation of C_6-compound into C_4-compounds (like butyric acid or butanol), ha not yet been solved. Two facts indicate that thi fermentation follows a different scheme: (1) the normal C_3-compounds, which are doubtlessly intermediate products in the other fermentations, do *no* yield C_4-compounds; (2) *pentoses* cannot be fermented by yeast whereas they are fermented by action of butyric organisms to the *same* C_4 products as are obtained starting with C_6-compounds. As method of approach to this problem a systematic research on the *structural conditions of the substrate molecule* leading to C_4-compounds through the bacterial enzyme has been carried out in continuation of previous experiments[1].

All experiments were made with a strain of *Clostridium acetobutylicum* (Weizmann). The same results were obtained with fresh bacteria (centrifuged after 24 hr., fermentation in 1 per cent maize mash, washed three times with physiological saline solution, suspended in phosphate buffer *p*H 6·2) as with acetone-dried bacterial preparations, which showed undiminished activity for at least one year. For analytical reasons only butyric acid was determined as essential C_4-product.

The C_1-atom of C_6-compounds does not play any part in the formation of C_4-products. Replacing the CHO-group of glucose by the COOH-group (gluconic acid), by the CH_2OH-group (mannitol, sorbitol) by introduction of phosphoric acid (hexose-*l*-monophosphate, Cori-ester), butyric acid was in all cases formed. On the other hand, replacing the CH_2OH-group at C_6 by the COOH-group (galacturonic acid), only acetic acid was obtained. Introducing phosphoric acid at C_6 (hexose-6-monophosphate, Neuberg-ester), only traces of butyric acid were formed. Using hexose-1,6-diphosphate (Harden-Young ester), only acetic acid was formed. Simultaneously, after some hours incubation, already appreciable amounts of methylglyoxal were observed. In this special case the sugar is therefore split into C_3-molecules.

Experiments with C_5-compounds showed, like hexoses, formation of C_4-compounds from *l*-arabinose and *l*-xylose. *d*-Arabinose was not attacked, but the corresponding *d*-arabitol formed C_4-products. *l*-Rhamnose gave also butyric acid. The C_4-compound erythritol was not decomposed by the bacteria.

The most important step was the investigation of the C_3-compounds. Phosphoglyceric acid, phosphoglyceric acid + glycerophosphate, *d,l*-glycerinaldehyde were not attacked at all; the latter even inhibited the fermentation of glucose. Pyruvic acid formed only pure acetic acid. Even in the presence of glucose, pyruvic acid formed *only* acetic acid.

Substrate	355·1 mgm. glucose	169·2 mgm. glucose 186·4 mgm. pyruvic acid	367·4 mgm. pyruvic acid
N/10 volatile acids (c.c.)	16·54	29·50	44·96
Ratio butyric/acetic acid	1 : 1	1 : 6	pure acetic acid
Butyric acid (mgm.)	72·78	37·08	

From these experiments it is concluded that pyruvic acid cannot be considered as an intermediate product for the formation of C_4-compounds. Davies and Stephenson[2] claim that butyric acid is formed from pyruvic acid. However, this result is in contradiction to my investigations. Koepsell and Johnson[3] recently published experiments with a cell-free water extract from cells of *Clostridium butyricum*. They obtained from pyruvic acid only acetic acid, carbon dioxide and hydrogen. The fact that this extract catalyses the evolution of gas from pyruvic acid but *not* from glucose forms a further proof for the view that the breakdown of pyruvic acid is *not* linked with the formation of C_4-compounds.

One single compound from the C_3-series yielded butyric acid, namely, glycerol. This shows that the formation of butyric acid must be a synthetic process, glycerol being condensed probably to a C_6-compound. It may be supposed that this condensation leads to a C_6-alcohol like mannitol and not to a C_6-sugar, as in experiments with alcohols (mannitol, sorbitol, arabitol, glycerol) the highest values for butyric acid were obtained. Further, it may be noted that Yamasaki and Simomura[4] isolated mannitol formed from glycerol by action of Aspergillus. It has already been established by Neuberg[5] and Iwasaki[6] that the C_3-compound dihydroxyacetone is not directly fermented by yeast but after previous condensation to hexose which could be isolated as hexose-monophosphate.

Glycolaldehyde was not attacked by the bacteria and even inhibited the fermentation of glucose. Sodium formate was not decomposed but had no toxic effect.

Conclusions: The obvious assumption that a similar enzyme system to that known to exist in yeast or lactic acid bacteria, which breaks down sugar into C_3-compounds, has to be discarded in favour of a different mechanism.

A detailed description of the experimental material will be published shortly elsewhere.

Specific Diagnosis of Typhus Fever by Rickettsial Agglutination

IN a series of publications[1], we presented data demonstrating that guinea pigs, rabbits and monkeys can be immunized with formolized tissue cultures of Rickettsia and that the murine, flea-borne and human louse-borne strains were antigenically distinctive, each failing to produce immunity towards the other. The latter findings were confirmed by Zinsser and Castaneda[2]. Recently Plotz[3] confirmed the antigenic difference between murine and human strains of Rickettsia by the complement fixation method.

Since the Weil-Felix reaction, based as it is on the presence of a common antigen, does not differentiate between the two forms of typhus, we tried to ascertain whether specific Rickettsial agglutination can serve this purpose satisfactorily. Such a specific diagnostic test is of special importance for epidemiological reasons, in a country such as Palestine, where murine typhus is endemic and where the invasion of epidemic or louse-borne typhus is imminent.

The results presented below show that the two types of Rickettsia are antigenically distinct, thus confirming the previous immunological findings. They also indicate that Rickettsial agglutination can be used for early differential diagnosis of the type of infection. The data are admittedly limited, but because of the urgency of such a test it was thought desirable to report our findings at this time.

Alcoholized, formolized and untreated, purified suspensions of Rickettsia in buffered saline (*p*H 7·4) were used. The suspensions were prepared from yolk-sack cultures and standardized at a density giving clear agglutination. The organisms were added to various dilutions of serum in buffered saline, in the usual manner, and readings made after four hours in a water-bath kept at 42° C., and again

TABLE 1.

Type of disease	Day of disease	Weil-Felix, max. titre	Murine strain, max. titre	Human strain, max. titre
Murine	5th	1 : 100—	1 : 100+	1 : 50—
	10th	1 : 200+	1 : 200+	1 : 50—
	16th	1 : 800+	1 : 400+	1 : 50—
Human	6th	1 : 100+	1 : 100+	1 : 200+
	10th	1 : 200±	1 : 100+	1 : 800±
	16th	1 : 200+	1 : 100+	1 : 800+

after 18 hours at room temperature. We used two murine strains—one from Tunis (*T*) and one from Palestine (*K*); and three human strains—a local strain isolated from lice (*L*), a louse strain from Addis Ababa (*A*), and a strain isolated from a patient who came from the U.S.S.R. (*R*).

In six confirmed cases of murine typhus (either laboratory infections or by animal inoculations), during the second week of the disease, the range of the Weil-Felix titres was 100–1,000, that with murine strains 250–400 and with the epidemic strains 0–100. In six confirmed cases of epidemic or human typhus, about the end of the first or beginning of the second week of the disease, the range of the Weil-Felix reaction was 0–200, the titre with epidemic strains 80–600, and that with the murine strains, 0–100.

In twelve additional cases from a group known to be louse-infected, the agglutination titres with human Rickettsia antigens were as follows: 4–1 : 80; 5–1 : 160; 3–1 : 320.

The course of appearance of agglutinins in two typical cases of typhus, one murine and one human, is given in Table 1.

Only one serum of those tested thus far, a Palestinian patient, gave an equally high titre, 1 : 640, with both murine and epidemic strains. The significance of such a divergent result can only be ascertained when a large series of confirmed cases has been tested.

The specificity of these reactions was substantiated in two series of animal tests, as well as by the agglutinin absorption technique. The sera of guinea pigs, which recovered from an infection with blood from patients or with known human or rat strains, were titrated against both types of organisms three to four weeks after recovery. Of six animals which passed a typical rat-type infection, the range of titre of the sera with the murine antigens was 200–80, while that with human strains was 0–100 (murine, 2–200; 2–300; 1–400; 1–800; human, 1–0; 2–20; 1–50; 2–100). Of nine guine pigs which passed a typical human strain infection the serum titres with the louse strains were 200–800 (2–200; 6–400; 1–800), while those with the ra strains were 50–100 (6–50; 3–100).

TABLE 2.

Sera	Antigens					
	Murine		Human			Weil-Felix
	K	*T*	*A*	*R*	*L*	
Murine						
K 1	200+	200+	100+	100±		
2	400+	200+	200±	100±		
3	800+	400+	200+	200±	50+	50+
T 1	100+	200+	50+	50+		
2	200+	800±	100+	50+		
3	200+	800+	100+	50+	100±	100+
Human						
A 1	50—	50—	100±	50±		
2	100±	100+	400±	100±		
3	100±	100+	800+	200+	400±	100+
R 1	50—	50—	50—	50+		
2	50+	100+	200+	600±		
3	100±	100+	200+	800+	400±	200±

Finally, rabbits were immunized with formolize vaccines of four specific strains, two murine and tw human, and the cross-agglutination of their sera with the homologous and heterologous strains determined The sera of none of these animals gave Rickettsi agglutination before the injections. Three injection were given at intervals of one week and blood wa taken before the second and third injections, an two weeks after the last injection. The titres of th various sera with the homologous and heterologou antigens are given in Table 2.

These results show that the various Rickettsia strains tested fall into two types or varieties. Th strains of the murine type are closer to one anothe than they are to the human strains, and vice versa On the other hand, it should be noted that the strain of the various type are not identical but show individual antigenic patterns.

Absorption tests substantiate these results. On murine (*K*), and one epidemic serum (*A*), was absorbed with the heterologous strains and the titre of the absorbed sera for all strains determined. Th results are shown in Table 3.

TABLE 3.

	Titre against antigens				
	Murine		Human		
	K	*T*	*A*	*R*	*L*
Serum *A* (human strain) absorbed with strains					
T	50	0	600	200	200±
R	100	50	400	0	100
A (control)	200	100	800	200	200
Serum *K* (murine strain) absorbed with					
T	200	0	100	200	50
R	200	100	100	0	0
K (control)	800	400	200	200	50

It seems, therefore, that the Rickettsias have divers antigenic patterns with gradations between th various strains. It appears that along with th distinctive characters of the broad variants, th strains within the group show considerable antigeni overlapping and differentiation. The significant finding is that different strains of a given type hav different antigenic elements. These findings have bearing on the nature and efficacy of prophylacti vaccines. It is evident that, for the time being a least, and until the ideal strains are found, a polyvalent vaccine is called for. No single strain of given type can be assumed to give full protectio against another from a different source.

Colour of Red Blood Corpuscles

I HAVE read with great interest recent communications on this subject which have appeared in NATURE[1]. I agree entirely with them, but another factor is, I think, involved, for when single red blood cells are looked at under a microscope they appear to be chrome yellow, lemon (barium) yellow or yellowish-green (crude auriolin) according to circumstances, whereas very dilute solutions of hæmoglobin look pale orange, beige or straw-coloured (yellow ochre) according to circumstances. In other words, there seems to be a greenish tinge visible in the cells which is absent from the dilute solution. Now, it is very easy for the eye to be misled in judging shades of colour when they are seen separately. Judgment is much more exact when the colours to be compared are seen side by side. This can be achieved in the following way.

Remove the eyepiece from an ordinary microscope. Unscrew the lenses and place them together so that they form a Ramsden eyepiece. Prick the finger and dilute the blood about 1 in 100 with normal saline. Place a drop of the mixture on a slide, cover with a cover slip and examine with a $\frac{1}{6}$-inch objective.

Prick the finger again, dilute the blood about 1 in 100 with distilled water. Place tiny drops of the mixture on a glass slide by means of a very fine paint brush. Place on a drop of xylol. Place this slide on top of the draw tube of the microscope. Examine the droplets with the Ramsden eyepiece, constructed as above, and focus the magnified images of the red cells at the same time. Shift the slides until a red cell and a droplet of solution are seen side by side in the eyepiece. The cells look greenish, whereas the solution looks orange; the difference in colour is usually quite striking. Droplets of different depths of tint may be tried, but none of them will be found to match the colour of the red blood cell.

The explanation is as follows. As is well known to the computers of optical objectives, the secondary spectrum due to uncorrected chromatic aberration tends to colour the edges of the images of all objects. The precise colours of the secondary spectrum depend on the two wave-lengths chosen for exact coincidence in the focal plane of the objective. In photographic objectives the colours of the secondary spectrum are often blue and yellow. In achromatic microscope objectives they are often blue-green and pink. In emi-apochromatic objectives they are often green and purple. These colours are well seen if an emulsion of two colourless fluids is observed with the microscope, uch as xylol vigorously shaken with water. The droplets should be colourless, but when seen under the microscope appear to be tinted green, blue-green or blue according to the objective in use, and to have surrounding them narrow rings which are purple, pink or yellow respectively. The precise colour of this surrounding ring is often obscured by other aberrations which are present.

Consequently, when objects such as cells are observed under a microscope the colour presented to the eye will be that which results from combining the absorption of the dye in the object with the secondary spectrum of the objective. In the case of red blood cells, the faint orange or straw yellow of the hæmoglobin is modified by the green, blue-green or blue contributed by the objective, as the case may be, causing the cells to appear yellow or even yellowish-green. In confirmation of this, experiment shows that when red cells are observed through a fully corrected apochromatic lens, their colour is no longer yellow or yellowish-green, but the unmodified pale orange or straw yellow of the hæmoglobin alone.

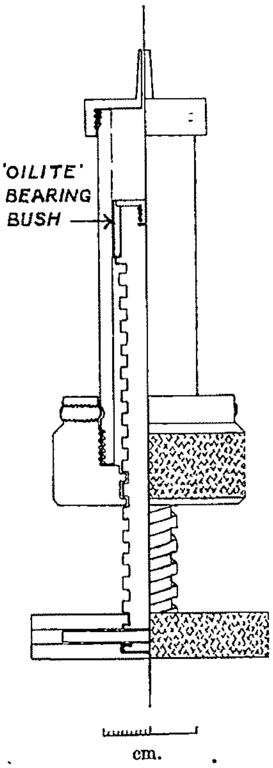
Intracutaneous Injection of Cattle

DURING the course of investigations on the production of immunity to foot-and-mouth disease the intracutaneous route of vaccination has been considered. It has generally been recognized that one disadvantage of this route in large animals is that, owing to the pressure required, only a small volume of inoculum can be injected at one site. Various attempts have been made in the past to overcome this difficulty, and by means of compressed air Curasson, Dischamps and Andryesky[1] found it practicable to inject 10 c.c. of their rinderpest vaccine into the skin of the bovine scrotum and vulva.

With an ordinary hypodermic syringe it is possible to inject up to 5 c.c. of a watery liquid into the skin of cattle, but the pressure required is too great to make the injection of a number of animals a very practical procedure; it is only with very great difficulty that a more viscous liquid such as serum or defibrinated blood can be injected in such a large dose. There is also a tendency with a hypodermic syringe for some of the inoculum to leak past the piston.

With the help of Dr. E. Schuster of the National Institute for Medical Research, Hampstead, a special syringe has been designed for this work. The principal difficulty of providing sufficient pressure has been overcome by making use of the mechanical power of the screw.

The salient features of this syringe are shown in the accompanying diagram. It is of metal construction. The capacity of the syringe is 10 c.c. and it is filled and emptied by turning the knurled wheel on the end of the piston rod, the pitch of the thread on the piston rod being so designed in relation to the bore of the barrel that one turn delivers 1 c.c. The syringe can be dismantled by loosening the grub screws on the collar, unscrewing the collar and withdrawing the piston from the barrel. It is essential that the piston fits the barrel very closely, and in order to prevent these two metal surfaces seizing, the sides of the piston are formed by an 'oilite' bearing bush. Such a bush consists of sintered bronze impregnated



with oil, and is normally used for providing a self-lubricating bearing. The purpose of its incorporation in this syringe is to provide a thin film of oil between the piston and the barrel. To avoid losing the oil from this 'oilite' bush the syringe must be assembled before sterilization. With an accurately fitted piston a pressure of 50 lb. per sq. in. can be easily obtained, and at this pressure there is only a slight and insignificant leakage of the inoculum past the piston. Brass and phosphor-bronze were used for the construction of this first model; but there is no reason why stainless steel could not be employed or the brass syringe could be cadmium plated. This is mentioned as it may be thought desirable to avoid the possibility of some of the metallic ions in these alloys exerting a deleterious effect on the inoculum.

By the use of this syringe it has been found that up to 10 c.c. of liquids of various viscosities can be readily injected at one site into the skin of the neck of cattle. A full account of this work will be published elsewhere.

I am indebted to Mr. M. Gilbee of the National Institute for Medical Research, Hampstead, for his painstaking work in constructing this syringe.

Boiling Point and Viscosity

IN connexion with the communication by A. Dutta[1] connecting the ratio of η/η_B with that of T/T_B, where η represents viscosity, T temperature and the suffix B the boiling point condition, and obtaining a 'universal curve' for several gases it may be of interest to add the following facts.

From considerations of the mechanisms of both viscosity and evaporation, a relationship was obtained in 1939 for liquids in which the ratio η/η_B was found to be a function of T/T_B, expressed graphically[2]. It was found that certain groups of liquids, for example, homologous series, fell on a common curve. Further, there were three distinct regions describing associated, metallic and normal liquids. The position of these curves were further governed by the 'shape' of the molecule, but the most important consideration was the evidence from a fuller report of this work than my note appearing in NATURE, that "one law governs all viscous flow in all states of matter and that there must be a solitary equation giving the change, with temperature, of magnitude of viscous forces in flowing matter"[3]. This was in contradistinction from the prevalent view that the mechanism of viscosity in liquids is essentially different from that of gases. To formulate this universal law governing the viscosity-temperature relationship, the general equation for liquids,

$$\log \eta = K + K_1\left(\frac{T}{T_B}\right) + K_2\left(\frac{T}{T_B}\right)^2 + K_3\left(\frac{T}{T_B}\right)^3,$$

was solved[4]. It was found that all paraffins containing four or more carbon atoms are governed by

$$\log \eta_P = 6{\cdot}283 - 18{\cdot}572\left(\frac{T}{T_B}\right) + 17{\cdot}505\left(\frac{T}{T_B}\right)^2 - 5{\cdot}900\left(\frac{T}{T_B}\right)^3,$$

and further, that for the other liquids the viscosit at the same value of $\left(\frac{T}{T_B}\right)$ as that for the paraffi was governed by

$$\begin{aligned}\log \eta &= A - B\,(6{\cdot}283 - \log \eta_P).\\ &= C + B \log \eta_P.\end{aligned}$$

Further[5], as

$$\log \eta = A\,f(T) + \frac{Q}{2{\cdot}3RT},$$

where Q is energy of activation of viscosity, therefor

$$\Delta\left(\frac{Q}{T}\right) = -\,2{\cdot}3\,R\,\Delta\left\{18{\cdot}572\left(\frac{T}{T_B}\right) - 17{\cdot}505\left(\frac{T}{T_B}\right)^2 + 5{\cdot}900\left(\frac{T}{T_B}\right)^3\right\}$$

Thus the energy of activation, for the viscosity o liquids, in parallel with that of evaporation, wa found to decrease, ultimately, with temperature an vanish at the critical point. This is due to the fac that the energy of activation is the result of tw energies, a positive and a negative energy, bot increasing with the temperature but at unequal rates becoming equal at the critical temperature. Abov the critical temperature the negative energy is o greater arithmetical value than the positive, indicatin a rise of viscosity of a gas with temperature. A this involves working under the pressure of th saturated vapour. For low pressures the influenc of pressure is negligible.

At the present time work is proceeding on passin from the liquid to the gaseous state through th critical temperature, in the hope that if the singl equation for all states works as well with gases a liquids under these conditions, it may be extende to vapours and gases under different conditions.

There appears to be no doubt that the use of T/T as a criterion for levels of temperature affords distinc possibilities to the understanding of the mechanis of viscosity—possibilities not so readily availabl using other 'reduced temperature' scales.

A Dental Survey of the British Isles

THIS is a general report on the effects of war-tim diet on the dentition of 9,400 youths in England an Wales, Isle of Man, Northern Ireland and Eire. I the last-named place until April 1943, meat, egg and milk, sweets and chocolate have not bee rationed; sugar and tea have since been controlle and butter only partially.

The scheme of assessment of dental decay employed in the investigation recognizes as bad or decayed, teeth extracted for orthodontic reasons, teeth lost as a result of caries or of accidents at games, and from all other causes. None the less, in the present survey only four cases were actually listed as due to accidents.

The factors controlling dental growth are proteins, fats, carbohydrates, minerals like calcium, phosphorus, iodine, iron, sodium, potassium, magnesium and copper; vitamins A, B, C, D; and hormone-secreting glands like the parathyroids. According to Fish[1] there is a factor, an immune saliva, a product of healthy general metabolism, which prevents dental decay and which is more frequently found in boys than girls. It is believed that excess of vitamin D is likely to lead to malformation of teeth, but Soma Weiss[2] denies the existence of any toxic effects from excessive administration of vitamins.

Vitamin A omitted from the diet will lead, among others, to infections of parodontal tissues and pyorrhœa. It is intimately connected with dental development.

The sources of the minerals and vitamins essential for perfect dental growth are dairy products such as eggs, butter, milk and cheese; marine fish and their oils; summer fruits, green vegetables and citrous fruits. "At the present time," wrote Prof. Mottram[3], "it looks as though the British diet may soon become deficient in first-class protein, iron and calcium and most, if not all, the vitamins."

The factors concerned in the etiology of dental caries are numerous, and even now are not all quite well understood. Miller of Berlin found that caries is due to *L. acidophilus*. Others maintain that gingivitis and dental decay may be due to food debris clinging to interdental spaces where the bacterial flora has optimal conditions for growth and multiplication. Most American workers hold the view that a pulpless tooth acts as a septic focus for the eventual infection and destruction of dental structure. Soviet workers like Entin of Leningrad and Lukomsky of Moscow reject the chemobacterial theory of American workers; but Entin believes in apical irritation, and Lukomsky in allergy, as etiological factors in caries. Both lay stress on diligently seeking means of preserving the teeth.

Lady Mellanby[4] found in 1929 that increased liability to dental disease and gross hypoplasia of teeth may be the result of defective maternal diet especially in mineral salts. N. Simmonds[5] states that the low incidence of dental caries among indigenous populations has not been the result of any one dietary regimen. Klein and Palmer[6,7] postulate the existence of caries immunes and caries susceptibles, but deny the influence of socio-economic status on the incidence of caries.

I believe that dental decay is due to the destruction of the dentine and enamel by bacteria, by refined foodstuffs like white flour, cereals, and white sugar, by chemical abrasives and by too frequently boiled milk, and occasionally by fluorine in drinking water.

In the accompanying table, of the total (9,400), 3,480 are from the public schools and colleges, 5,770 are factory girls and the rest from two model elementary schools.

No. of teeth lost	0 %	1 %	2–3 %	4+ %
Public Schools (ages 12–18)				
English boys	61·18	13·14	15·98	9·60
English girls	46·96	17·49	21·16	14·39
Welsh girls	48·64	14·25	21·05	16·06
Manx girls	62·00	7·00	17·00	14·00
North Irish boys	53·76	19·36	19·84	7·04
North Irish girls	57·00	16·67	19·47	6·86
Eireann boys	62·50	14·58	15·27	7·65
Eireann girls	50·87	16·37	24·00	8·76
Post Public Schools (ages 19–22)				
English T. Coll. girls	21·70	17·84	27·13	33·33
North Irish Elementary Schools (ages 10–14):				
Boys	41·50	27·00	23·50	8·00
Girls	55·00	20·00	15·00	10·00
Factory girls (N.I.) (ages 14–24)	10·00	5·00	35·00	50·00

It is obvious from the peculiar nature of the problem we set ourselves that any conclusions we may arrive at must form the point of departure for subsequent workers since there are no previous comparable data to work on. We may, we believe, safely infer from this sample that at least until July of this year (1943) war-time diet, scarcity of sugar, sweets and chocolates have had no damaging effects on the nation's teeth since the dental status of English boys and Manx girls approximate that of Eireann boys. It also follows that abundance of sugar and sweets has in no way destroyed the dentition of Eireann students.

It is only when we compare English college girls with English public schoolgirls, and Northern Irish factory girls with their schoolgirls, that gross differences in improvement of the younger generation become apparent. It is statistically significant that in both Eire and England more boys have perfect teeth than girls.

I gratefully acknowledge my indebtedness to Dr. R. L. Wilbur, chancellor of Stanford University, Dr. N. Simmonds of the College of Dentistry in the University of California, Miss Slane and Dr. F. Boudreau of the Milbank Memorial Fund of New York, Mr. L. McKenzie and Dr. W. McTavish of Upper Canada College, Toronto, for their kind interest and generosity in freely placing at my disposal, recent publications on child health issued by their several institutions.

I wish to express my sincere thanks to the principals, headmasters and headmistresses of the following schools in England: Rugby, Repton, King's College (Taunton), the Abbey School (Malvern), Edward Brooke's (London), Chelsea Polytechnic, Liverpool Training College, Felixstowe College, Bishop Blackall's (Exeter), Notre Dame Collegiate (Liverpool). In Wales, Howell's School (Denbigh), Howell's (Llandaff and Cardiff). In the Isle of Man, Buchan School (Castletown). In Northern Ireland, Londonderry High School, Collegiate School for Girls (Enniskillen), Coleraine Academical Institution, Technical High School of the College of Technology (Belfast), the Model Elementary Schools of Omagh and Enniskillen. In Eire, St. Columba's College (Rathfarnham near Dublin), High School (Sligo), Celbridge Collegiate School (Co. Kildare), Drogheda Grammar School.

R. E. G. ARMATTOE.

7 Northland Road,
Londonderry.

RESEARCH ITEMS

Tularæmia in Shrews

Glen M. Kohls, assistant entomologist, and Edward A. Steinhau, associate bacteriologist, confirm (*Public Health Rep.*, 58, 842 ; 1943) the occurrence of spontaneous tularæmia in the shrew (*Sorex vagrans monticola*) and the field mouse (*Microtus pennsylvanicus modestus*) by the following examinations of the animals. Three shrews and ten field mice were caught in traps. No gross lesions were found at autopsy, but the spleens and livers of each species were pooled and injected into four guinea pigs which died from six to twelve days later with gross lesions suggestive of tularæmia. *Pasteurella tularensis* was isolated from the spleen and liver of two of the guinea pigs given the shrew tissues and in three of those that received the field mouse tissues.

Tyroglyphid Mites in Stored Products

Tyroglyphid mites, which include cheese mites and flour mites, infest most kinds of stored products. They are common also on mushrooms and in laboratory cultures of insects. A vast amount of scattered information exists regarding these creatures, much of which is valuable but greatly in need of being collated and made more readily accessible. As a guide and introduction to the study and control of these mites a recent pamphlet by M. E. Solomon entitled "Tyroglyphid Mites in Stored Products", published by the Department of Scientific and Industrial Research, is to be commended (London: H M. Stationery Office, 1943. 9*d*. net). The knowledge thus brought together is well arranged under suitable headings and there is a bibliography of about 250 references. With few exceptions, the literature of the nineteenth century has been omitted, since it is listed and discussed in the well-known monograph of British Tyroglyphidæ by A. D. Michael. In the discussion at the end of this pamphlet it is pointed out that a long-standing need is for a unified system of classification with complete keys to the genera and species. This desideratum has to a great extent been fulfilled by the work of Zakhvatkin (1941). Its complete translation from the Russian would considerably assist British workers. The importance of moisture in the ecology of these mites is stressed. As a control measure, dry-storage of susceptible products is of first importance. There is also need for quantitative data on the rate of increase and damage done by mites under different conditions. Another requirement is more critical work on control measures, with special reference to the resistant egg and hypopus stages.

Feeding Apparatus of Biting Flies

R. E. Snodgrass has described and figured the mouth-parts of biting and disease-carrying flies as a war-time contribution to medical entomology (*Smithsonian Misc. Coll.*, 104, No. 1 ; 1943). As the author points out, most text-books of medical entomology do not describe the feeding organs of such insects in sufficient detail to be adequate. The present paper is intended to supplement such texts and thus to make available to teachers and students a condensed but detailed account of what is known to entomologists concerning the mouth-parts of the kinds of flies mentioned. The author has drawn freely upon modern literature on the subject besides incorporating observations of his own. As he points out, some of the most thorough investigators are specialists in a particular group, and do not give sufficient attention to other insects to make reliable interpretations of the homologies of some of the organs involved. A case in point is the use of the term *tormæ* by so many writers with reference to the anterior plate of the fulcrum. As pointed out by Patton and Cragg and also by Imms, this plate is the homologue of the clypeus of other insects. The memoir brings together, within convenient compass, a detailed account of the organs concerned, together with a number of clearly executed text figures, the majority being original. It can be recommended to investigators and teachers alike. A bibliography of the more modern literature on the subject is appended.

The *Rh*-Factor of Blood

It has been recently shown that the dominant agglutinable factor *Rh* of blood is associated with a specific disease of the newly born and that stillbirths and abortions may result from the interactions of the blood groups of mother and fœtus. P. Levine (*J. Hered.*, 34, 71 ; 1943) summarizes recent work and indicates that anæmia of the newly born, erythroblastosis fœtalis, results from genetic differences in the antigenic compositions of the erythrocytes of the parents. The actual mechanism depends on the iso-immunization of the mother by the *Rh*-factor in the blood of the fœtus and the intra-uterine interaction of maternal anti-*Rh* agglutinins on susceptible fœtal blood. Evidence is presented which indicates that other blood group factors may also be responsible for some forms of fœtal death (see also Nature, September 11, p. 300).

The Phæophyceæ

In the third paper of the series "Studies in the Comparative Morphology of the Algae", F. E. Fritsch discusses the possible interrelationships of the orders in this group (*Ann. Bot.*, 7, No. 25 ; 1943). The assemblage of forms included in Oltmanns' Ectocarpales (except the oogamous Sporochnales and Desmarestiales) illustrates experiments in elaboration of the diploid thallus, the most important of which is probably the development of polystichous (parenchymatous) forms by the appearance of division walls in various planes in the cells of the primary, heterotrichous thallus. In this group the growth is usually intercalary (trichothallic), but some members relatively early lose the part distal to the meristem and assume apical growth ; this point may be significant when considering the interrelationships of forms with apical and intercalary growth ; in Fucus the apical cell of the adult plant is preceded by a hair with intercalary growth in the juvenile stage. In spite of pointers of this kind in the Ectocarpales, Fritsch concludes that the more specialized orders have no direct affinities with one another and must be regarded as separate evolutionary lines emanating from simple filamentous forms with an isomorphic life-cycle. The lines of development accompanying the heteromorphic life-cycle show the higher degrees of somatic differentiation. The tabulated scheme indicates markedly the isolation of some of the orders. The higher orders receive independent discussion and comparison. The Tilopteridales still remain a problem in classification : Sauvageau's original contention, that the monosporangia on plants of either generation represent accessory asexual reproductive organs, seems to be supported by the more recent observation of larger, amœboid units liberated from lower compartments of the plurilocular sporangia of Tilopteris; possibly these may be female gametes and be equivalent to the swarmers liberated from the relatively large compartments of plurilocular sporangia of Acinetospora. Within comparatively recent years a considerable amount of literature has appeared, particularly in connexion with brown algæ, and these papers by Prof. Fritsch are very valuable in bringing the new work, some of which is in journals not always readily accessible, under discussion in a review of the present position of our knowledge of the algæ.

Taxonomy and Distribution of the Fungi

An interesting computation of the numbers of fungi by G. R. Bisby and G. C. Ainsworth (*Trans. Brit. Mycol. Soc.*, 26, Pts. 1 and 2; April 1943) places the world total at 37,500, of which about nine thousand have been recorded from Great Britain. These numbers are subject to constant addition, and in the same *Transactions*, two new species belonging to the mould genus Aspergillus are described by G. Smith. They are *A. avenaceum*, from dried peas, and *A. proliferans*, isolated from cotton. No special characters likely to be of use in industrial chemistry are reported, though the genus is otherwise rich in such activity. A further new species, *Sphaceloma Murrayæ*, is also described by Anna E. Jenkins and Leon Grodsinsky from New Zealand. It causes a destructive disease on willow, and was formerly considered to be a species of Glœosporium. A. A. Pearson, in the same journal, describes twenty-three new British records for Agaricaceous fungi, or species for which further descriptions are now available. They belong to most of the commoner genera, and two new combinations, *Astrosporian umboninota* and *A. Boltonii*, are perhaps of special interest since their extraction from the genus Inocybe is based upon well-defined spore characters. A very detailed account of British Nectrioideae and allied genera by T. Petch, published in the same volume, considers the highly coloured forms of Saccardo's assemblage the Sphaeropsideæ. It is chiefly a modern evaluation of von Höhnel's work on the same groups, with useful keys and descriptions of type-species.

oil Pests of the Potato

A short paper by G. Fox Wilson (*J. Roy. Hort. Soc.*, 68, Pt. 7; July 1943) describes several insect pests which live in the soil and attack potato tubers. Wireworms, slugs and millepedes are all too common visitors; but leather-jackets, cockchafer grubs and utworms also cause damage. Particular interest is ttached, however, to the inclusion of swift moth aterpillars as potato pests. These were formerly thought to feed mainly on the roots of grasses, but most horticultural advisers would agree with Mr. Fox Wilson that they have recently exhibited more predatory tendencies upon several food crops, including potatoes.

ariations in Radioactive Data

Information concerning the distribution of the adioactive elements in rocks is of fundamental eophysical importance because of the influence of adiogenic heat on the thermal behaviour and history of the earth. A report on recent work bearing on the causes of variation of such radioactive data has been given by N. B. and A. R. Keevil, W. N. Ingham and G. P. Crombie (*Amer. J. Sci.*, June 1943). The greatest differences—indicating variations in radioactive content by a factor of fifty or more from specimen to specimen—occur in certain granitic rocks, due mainly to varied concentrations of accessory minerals, chiefly zircon and apatite, which are often highly radioactive. It has also been discovered that in the case of the Bourlamaque batholith, Quebec, there is a marked concentration of the radioactive elements towards the border of the mass. The contact rocks of this area are also exceptionally radioactive, and since they are highly albitized and silicified it is reasonable to attribute the enrichment to diffusion of material from the batholith. Regional variations are less pronounced, but it is clear that certain provinces, as in Colorado and the Great Slave – Great Bear region, are relatively highly radioactive, whereas others, such as parts of Ontario and Quebec, are relatively barren. In sedimentary rocks the effect of mixing of materials from different sources tends to produce uniformity of radioactive content. It is clear from the general results of the survey that many more data from representative areas are necessary before the laws governing the distribution of radioactivity in the earth's crust can be fully elucidated.

Short-Period Erratics of Free Pendulum and Quartz Clocks

W. M. H. Greaves and L. S. T. Symms have discussed their investigations of the performance of Shortt clocks and quartz-controlled clocks during 1942 (*Mon. Not. Roy. Astro. Soc.*, 103, 4). The work is limited to short-period erratics, but recent developments suggest that the superior performance of the best quartz-controlled clocks extends to long-term performance. Three types of erratics were recognized. The first of these represents accidental erratics in the clocks themselves arising from random fluctuations, about a mean value, of the phase at which the seconds impulses are taken, and also includes errors of chronographic recording and measurement. The second type, accidental errors affecting the first differences, may arise from accidental fluctuations of rate about a mean value, or from accidental changes of phase, and it is impossible to distinguish these two kinds of erratics. The third type affects second differences and arises from accidental changes of rate. For clocks of the standard free-pendulum type, all three types of erratics are present in appreciable amounts, but for the quartz clocks the erratics of the second and third types are too small to be detected by the analysis, and erratics of the first type are predominant. The origin of erratics of the last type is obscure, but they exist in pendulum clocks, and as their effect on clock errors is cumulative, they are the most serious from the point of view of long-period performance. The second type of erratics also tends to produce a cumulative effect on clock errors, but, so far as long-period performance is concerned, they are not so serious as the third type. The first type of erratics does not affect the long-period performance of a clock. In so far as the long-period performance of a clock arises from the integrated effects of the short-period erratics, it is concluded that good quartz clocks are very superior in long-period performance to the best clocks of the standard free-pendulum type.

POST-WAR RELIEF IN EUROPE

IN opening a Conference, organized by the London Area Committee of the Association of Scientific Workers, on "Problems of Freed Europe—the Challenge to Medical Sciences", held on October 2, the chairman, Dr. Douglas McClean, pointed out that the task is one in which many aspects of science are deeply involved. Obviously experts in nutrition, agriculture, veterinary science and the medical sciences will have a considerable part to play in restoring reasonable standards of life; no less important will be engineers, architects, economists and a host of other trained people. It was the purpose of the Conference to direct attention to this point of view, to consider what the needs are likely to be, what mechanism and plans already exist, and in what ways they can be modified and improved.

The first part of the Conference was devoted to reports, from representatives of several Allied or occupied countries, describing the existing conditions so far as they are known. Dr. B. Kruta, chairman of the Czechoslovak Nutrition Committee, detailed the progressive diminution of supplies following the German occupation. The country was previously largely self-supporting in its food production; the producers are compelled to contribute quotas to the State-controlled retail corporations, with severe penalties for non-compliance, but are allowed to retain part of their produce for themselves, their families and animals, and for seed. The townsfolk are worse off in that they have fixed nominal rations but have no guarantee of actually being supplied. The general diet is deficient in fats, in vitamins and in energy content by 500–800 calories a day; the total protein content is low—about 40–50 gm. a day, of which only about 10 gm. is first-class protein. The greatest deficiencies occur in the diet of adolescents. The obvious malnutrition is accompanied by all the attendant increase in ill-health and disease.

Dr. A. Marteau told of similar, but even worse, conditions in Belgium where the bulk of the population has to exist on half a pound of poor-quality bread, 1 lb. of potatoes (in very irregular supply) and, when available, a few vegetables and 1 oz. of meat a day. Coupons for fats are issued, but the rations can often not be obtained. The position in Greece, reported by Dr. A. P. Cawadias (president of the Greek Red Cross) can only be described as complete famine, due mainly to the fact that the country normally produces only a very small proportion of its food requirements and is of very little value to Germany industrially or as a source of raw materials; its inhabitants are, therefore, not worth feeding. A certain amount of relief, equivalent to about 700 calories per head per day, has been reaching Greece since the spring of 1942, but it is quite inadequate to prevent the diseases of malnutrition and the epidemics which are rife.

Prof. S. A. Sarkisov (Soviet Red Cross) gave a picture of the tremendous amount of destruction of every sort which has followed the German invasion of the Soviet Union. Horses, cattle, sheep, grain and other foodstuffs in vast quantities have been removed, agricultural land put out of cultivation and buildings and machinery destroyed. As a consequence there is the usual tale of famine and disease. Already in the areas which have been liberated by the Red Army the work of restoration of hospitals and medical centres, housing and agriculture is proceeding. Feeding centres, public baths, kitchens, bakeries and sc on are set up immediately, and medical centres, with their supplies and equipment, as soon as possible.

Prof. J. R. Marrack then dealt with the present plans for relief. The problem after this War will be greater than after the last as more primary production centres have been involved and the East will also have to be considered. On the other hand, the Allied Post-war Requirements Bureau has been assessing the needs in food, medical supplies, seeds, livestock, etc., which will arise after the War, whereas, in 1918 relief had to start without plans. In addition, the United Nations Relief and Rehabilitation Administration (UNRRA) is being built up in order to deal with the problem. UNRRA will have power to distribute such stocks as may be available and to make appropriate plans, but will not have overriding power to obtain food, raw materials or shipping for transport The actual amounts needed will be small compared with total consumption of the United Nations and in most cases, could be provided readily if rationing in those countries were continued for a time after the War. Controls on transport would also need to be maintained in order to provide the means of getting the supplies to the people needing them. This should be the function of a Supreme Economic Council.

Mr. F. Le Gros Clark, in opening the discussion maintained that one of the chief duties of the relie organizations will be to co-operate with the national on the spot. Imports of all sorts should be made available as an inducement to local producers to par with surplus stocks and to remove the motive for and profit from, hoarding. Great care will be necessary in selecting personnel in order to avoid maladministration. Dr. Geoffrey Bourne pointed out that the occupied countries could be grouped according to the severity of their deficiencies determined by thei degree of self-support and the use of their industries to Germany. The main shortages everywhere are in calories, calcium, vitamins and first-class protein. Dr Bunting considered that one of the chief problems will be the restarting of agriculture and said that th problem will vary with each country liberated and with the season at which it occurred. He suggested tha local crops should be retained for seed, since they suit local conditions, and that imported produce should be used for food. Mrs. Bamford (of the Fabian International Bureau) stressed the importance of no allowing the withholding of relief to be used fo political blackmail. She agreed with Prof. Marrack that production and distribution should be under the control of a Supreme Economic Council and tha rationing should continue on the principle of "bread for all before cake for any".

Dr. Mark Daniels and Mr. W. D. Hogarth discussed the need for training personnel and the methods by which it could be achieved with th minimum of dislocation of the present position. Welfare workers have the requisite basic training, on t which special requirements could be fairly easily an quickly grafted. Dr. Ungar is of the opinion that mobile teams of physicians, bacteriologists, etc., wi be needed to deal with epidemics wherever the might break out. Dr. Kuczynski maintained that Germany must play its part in reconstruction by providing medical supplies, vitamin preparations instruments and so on, as well as general industria relief.

Dr. S. C. Dyke (president of the European Association of Clinical Pathologists) proposed that the Conference should pass a resolution urging on the overnment that there should be no relaxation of ationing until the needs of occupied Europe have een supplied. Mr. Le Gros Clark introduced an mendment that, as an essential preliminary, a wide ampaign of education be undertaken to explain to he public the necessity for such a measure. The mended resolution was carried with acclamation.

ATIONS AND FOOD CONSUMPTION IN SWEDEN DURING 1942-43

By CARIN BOALT and YNGVE ZOTTERMAN
rbetsfysiologiska Undersökningen, Karolinska Institutet, Stockholm

AN investigation of the individual food consumption of fifty-two households and one mbermen's canteen in Sweden has been made during he winter 1942–43. In seventeen of these households he breadwinner was a lumberman, in twenty a millorker, and in fifteen households a clerk in a factory r a bank. Thus men doing physically heavy outdoor ork, heavy factory work and very light indoor work ere represented. The total number of persons conrned was 212, of whom 76 were men, 59 women nd 77 children under fifteen years of age. The nvestigation continued for fourteen successive days, uring which the subjects weighed and checked all od eaten. Moreover, a complete account was kept ver household purchases of food and the food ceived in kind.

From these data calculations were made of the nsumption of different foods, the supply of the ore important food factors, the cost of food and e diet. This material makes possible comparative quiries into the influence of occupation, age and x upon the diet and standard of nutrition.

The lumbermen showed the highest consumption energy, with an average of 4,600 (large) calories for 4 hours, thereafter came the millworkers with 3,800 lories, and far behind them the clerical workers ith 2,600 calories. The women's consumption of ergy was 2,500 calories for lumbermen's wives and 200 calories for the other groups. The children's ergy consumption increased linearly with age. A ale of food energy standards has been worked out the basis of these results. This showed that the ildren's consumption of energy was higher than at was earlier reckoned on, while on the other nd the women's consumption was lower.

From the body-weight, height, age and sex, the sal metabolism of each subject was calculated cording to well-known empirical formulæ. In order to illustrate the influence of the occupation upon the energy metabolism, we have worked out what we call the activity quotient, namely,

$$\frac{\text{energy supply (net)} - \text{basal metabolism} \times .100}{\text{basal metabolism}};$$

in other words, the energy supply exceeding the basal needs was expressed as a percentage of this latter value. This quotient proved to be for the lumbermen 186, for the millworkers 132 and for the clerical workers 67 per cent. The total activity in regard to the physical work done in 24 hours thus varied as 3 : 2 : 1. The women showed in this respect a low activity quotient with 76, 59 and 58 per cent for, respectively, the lumbermen's, the millworkers' and the clerks' wives. The children showed a great dispersion ; no differences could be traced between boys and girls.

Comparisons between the consumption and the rations showed that the lumbermen exceeded their rations of flour and grain as well as fats by an average of 60 per cent. Even the millworkers exceeded substantially their rations of these foods, whereas the clerical workers and the women lived within their rations. For the youngest children, generally speaking, consumption was considerably below their allotments.

The investigation has accentuated the desirability of a strongly differentiated system of food rationing where the greatest possible consideration should be given to occupation, age and sex. A general principle during partial rationing should be to balance the rations so that an individual's energy requirement can be covered by a reasonable consumption of free foods. Thus it was shown that millworkers, whose rations gave 2,000 calories per day and whose energy consumption was 3,800 calories, received 2,500 calories from rationed foods and only 1,300 calories from free foods. Probably we must therefore reckon with the fact that in practice not more than 1,500 calories might be taken from such foods as milk, potatoes and other roots, which during the winter 1942–43 were not rationed in Sweden.

DAILY RATIONS IN SWEDEN IN FEBRUARY 1943

	Meal and grain (gm.)	Fats (gm.)	Meat (gm.)	Sugar (gm.)	Peas (gm.)	Cheese (gm.)	Eggs (gm.)	Calories contained in the daily rations
Children born 1942–43	152·0	35·7	14·3	60·6	8·0	4·2	5·4	1146

Ordinary rations	193·7	35·7	28·6	60·6	8·0	4·2	5·4	1334
Heavy workers	360·3	53·6	28·6	60·6	8·0	4·2	5·4	2060
Lumbermen living at home	443·7	53·6	57·1	60·6	8·0	4·2	5·4	2736
Lumbermen not living at home	402·0	53·6	55·6	100·0	18·7	4·2	5·4	2781
Pregnant women	193·7	53·6	28·6	60·6	8·0	32·8	22·5	1569

As concerns the children's consumption, certain foods, as, for example, flour and meat, showed a high correlation with age, whereas other foods such as milk and sugar did not show any increase with age. Among the adults there were great quantitative differences in the consumption of different foods between men and women in workmen's households. In the households of clerical workers, men and women had a very uniform diet.

The protein supply for men and children was kept well above the desirable level, while the women on average just reached this level, which means that a considerable number of women did not receive the desirable supply of proteins. This was particularly the case among the millworkers' wives. The supply of calcium and phosphorus was in the main satisfactory for all groups, whereas the consumption of iron among the smaller children and the women was below the desirable level.

The vitamin A supply showed a very wide dispersion. Starting from a minimum requirement of 2,000 I.U., the supply of vitamin A to the men of all three groups was above this value. The optimal supply of 4,000 I.U. has not been reached by any but a few lumbermen. Only one fourth of the number of the children seemed to have reached the optimal level for their age. With regard to the supply of vitamin B, the minimum and optimum requirement for adults is generally given as 0·75–1·50 mgm. vitamin B per day. The women and children have, on the average, not reached this optimum, and a few women showed a consumption below the minimum requirement. The supply of vitamin C was for all groups in the main above what has been considered to be the minimum, namely, 25 mgm. per day. The mean values for all groups of adults except those for the millworkers' and the lumbermen's wives were greater than 50 mgm., which is generally considered as the optimum. Among the children the supply of vitamin C was only exceptionally below 20 mgm. The mean value was about 40 mgm., but the dispersion was very great. The supply of vitamin C did not show any correlation with age, in contrast to the consumption of vitamin A and B, which increased linearly with age.

In conclusion, it can be said that the diet of our subjects seemed to be relatively satisfactory according to generally accepted ideas.

The women's consumption of food was, however, so small that their intake of iron and of vitamins A and B became rather low. The fact is, however, that the relation between the energy metabolism and the requirement of the different food factors is not as yet sufficiently well known to permit us to draw any safe conclusions concerning the women's nutritional standards. The same is the case in regard to the children's requirement of minerals and vitamins at different ages.

The money value of the food has been computed for all household groups and subjects by adding together the cash outlays for food and the value of the produce received in kind. The cash outlays for food for fourteen days amounted to 48 Sw. crowns for the lumberman's household, 51 crowns for the millworker's household and 71 crowns for the clerical worker's household, which was equivalent to 53, 39 and 28 per cent of the respective cash income. The total value of the food amounted to respectively 75, 58 and 76 crowns.

The cost of the daily food was on the average 1·73 crowns for the lumberman, 1·96 crowns for the millworker and 1·70 crowns for the clerical worker. The cost of food per 1,000 calories was respectively 0·38, 0·52 and 0·65 crowns.

Concerning the children, the food cost for the young children was about 0·90 crowns a day and for the school-children about 1 crown a day. The increase with age was thus inconsiderable. On the other hand, the food cost for the children belonging to clerical workers' families increased from 1 crown to 1·50 crowns. These children enjoyed also a relatively more expensive diet than the children of the manual workers. Thus the price per 1,000 calories for young children belonging to clerical workers' households was 0·73 crowns, whereas food of the clerical workers' young children cost about 0·50 crown.

These figures might be taken as an expression for the difference in the standard of diets between the household groups in question. The lumbermen's households, where the men as well as the women and the school-children showed a higher food consumption than in the other household groups, lived upon a cheaper diet, which, however, in qualitativ respect was not inferior to that of the other groups Their diet was, however, rather monotonous. Th clerical workers' households, which showed the lowest food consumption but the highest food expenses, showed, however, from the qualitative aspec a standard which was only insignificantly higher Their diet was, however, much more varied, which among other things expressed itself in their choice of dishes and variation in the way of preparing them

The cost of this investigation has been defrayed by grants from the Swedish Co-operative Wholesal Society, the Swedish Trade Union Congress, th Swedish Metal Workers' Union and the Wallenberg Foundation.

THE ELM TREE

By ALEXANDER L. HOWARD

THE elm tree, which on account of its peculiar habit of growth has become an outstandin feature of the English countryside, of which the genius of both British and Continental painters hav taken full advantage, seems doomed to extinction the tree is beset by too many enemies. With the breaking up of the large estates there is n one left to preserve it. For upwards of one hundred years no Government has existed in Great Britain which has shown any well-defined interes or devoted any tangible efforts towards reafforestation, and only in the course of the last twenty years or less, has the subject been given consideration Even during this period the main effort has been directed towards the financial rather than the nationa aspect.

It is interesting and instructive to contrast the labour and pains taken by those who preceded us—Virgil, Pliny, Evelyn and others—to ensure a plentifu supply of trees with those feeble efforts which ar practised to-day. For upwards of two hundred years few foresters have studied the means of the reproduction of elms, or the dangers imminent to the young trees, although we have possessed the knowledge of every kind of device, with explicit instructions as to how to plant, rear and establish them.

Although the life of the elm may be sustained fo upwards of six hundred years, and it is rarely struc by lightning, it is very liable to be blown down The roots, travelling horizontally, will not hold dow their weight. At an earlier age than other trees th elm is apt to become rotten at the heart. The tre is a prey to elm bark disease, which is very destructive; and what is worse, man has been very crue and unkind to it. As an example of disease, th beautiful avenue of elms in Windsor Park has bee condemned as beyond recovery. The wood, althoug ill-considered and costing less than that of mos hardwood trees, is, nevertheless, extremely useful and indeed more generally employed than is commonly known.

There are about twenty species, of which onl two are prominent in the United Kingdom—the common elm (*Ulmus campestris*) and the wych elm (*Ulmus montana*)—with perhaps nine or more hybrids or varieties. Whether the common elm or its varieties have been introduced or are indigenous to Great Britain is in doubt, but it seems generally accepted that the wych elm is indigenous.

The common elm was largely planted by our forefathers as roadside trees and avenues, and has become especially prominent in our hedgerows, while the latter has been extensively cultivated around the stately mansions and in parks throughout the country.

Boulger says of the wych elm :

> "Though more abundant to the north of the Trent, it is, wherever it occurs, less distinctly a hedgerow tree han its congener, though its name *montana*—the Mountain Elm, which seems to have been applied to it in very ancient times, is not very appropriate."

Strutt says in his "Sylva Britannica" that the common elm is indigenous to England, and we hear hat the Romans made a practice of feeding their cattle on its leaves—a use which would probably urprise the extravagant farmer of a later age.

Evelyn, in his "Sylva", says of the Dutch elm, which he terms *Ulmus Hollandica* :

> 'was brought from Holland about the beginning of the reign of King William, and was employed in forming edges in gardens ; but that taste being now justly exloded, the tree is no longer noticed in this country."

Evelyn states that

> the Wych Elm [which he calls] *Ulmus campestris*, is the only species that grows in Great Britain, the rest eing varieties."

Other authorities do not appear to agree with him. As regards his statement that the Dutch elm "is no onger noticed in this country" his opinion may have een well founded in his time, but to-day great numbers of Dutch elm (*U. major*) are to be found in the woodlands, gardens and parks of the landed entry and municipalities. Of late years the wood f the Dutch elm has been sought in preference to ither that of the common or the wych elm, but it is oubtful if in general it serves so many useful purposes as the wood of the latter.

As has been seen, according to Elwes the common elm is termed *U. campestris*, the name originally given by Evelyn to the wych elm. Elwes quotes as ollows :

> "John Harrison, nurseryman at Cambridge, plainly means *U. campestris* by the English Elm, in his New Method, 33 (1766): 'That which we call the English Elm, is peculiar only to the southern part of this island, where it grows wild in hedgerows : there is not a trace of that kind to be seen in the northern counties, but what has been planted within seventy or eighty years ; and these are either in avenues or some plantations near entlemen's seats.' "

Elwes also gives an account of a very remarkable elm at Huntly Manor, Gloucestershire, the seat of Mr. R. St. John Ackers, which has a watercourse running through the middle of the root. He says :

> "Mr. Ackers tells me that if you put a ferret into the oot on one side, it can pass through and come out on he other, which shows that the butt is partly hollow, hough the tree looks sound and is about 100 feet high. It is difficult to explain the origin of this curious freak."

ccording to Boulger the common elm is *U. surculo'sa.*

Authorities differ as to the origin of the term 'wych', sometimes spelt 'witch', and it has been sometimes, especially in the south, called 'wych hazel', the word 'hazel' having been applied probably owing to the fact that the leaves resemble those of the hazel, while the name 'wych' may have been taken, as Dr. Prior thought, from the early English 'hwaecce', the French '*huche*', a chest, our modern 'hutch', the wood of this tree having been used for these purposes.

Boulger refers to the origin of the name wych elm, and quotes Turner in his "Names of Herbes" (1548) :

> "Vlmus is called in greeke Ptelea, in englishe an Elme tree, or a Wich tree, in duch ein Vlme baume, or Ylmen or Rust baume, in frenche Orme",

the latter name 'rust baume' being the common name by which the wood is known in those countries where it is used more extensively than here, namely, Austria and Hungary, to which reference will be made later.

The habit of the two trees differs widely, the beauty of the common elm being in its unusual and distinctive manner of growth, forming somewhat the appearance of a series of rows of green sprays, one above the other at intervals ; while the habit of the wych elm is majestic and stately, the branches adorned by deep green leaves, which spread in graceful sweeps from the noble crown, descending often to the very ground beneath. The foliage again varies : in the early spring the common elm displays tender shoots which are almost of a purple colour, turning later to a vivid green, and changing in the autumn to a golden tint, while those of the wych elm hold their dark green colour throughout. A very graceful specimen of this tree may be seen in full vigour by the wide road across Rotten Row, in Hyde Park, London.

The Cornish elm, named by Evelyn *Ulmus sativa*, and by Elwes *U. stricta*, must not be overlooked. It will not compare with the common or wych elm for beauty or majesty. While it may perhaps be suitable for avenue trees for towns and villages, since the trunks or branches are not so apt to break away, it has otherwise little attraction. Of all the species we have, the wood of the Cornish elm is the nearest approach to that of the Canadian rock elm (*U. racemosa*) ; but perhaps while it is useful for a great number of purposes, it is not so suitable for boat boards as the wych elm.

While the timber of the elm has been the least costly of any hardwood obtainable, and consequently has been in large demand, the uses for which it has been employed have been greater than of any other British-grown hardwood. For the making of coffins immense quantities have been consumed. In the days of wooden ships it was used for keel pieces and in places where it would be in contact with the water, being eminently suitable for both these purposes. The builders of a modern ship, built in 1928, made use of an oak keel piece, bolted to the iron keel by iron bolts, measuring three feet long by three quarters of an inch in diameter. The ship being hauled up for repair, the keel in September 1943 revealed that while the iron bolt was perfectly sound in that portion which had not been in contact with the oak, twelve inches of the rod where it was in contact was entirely disintegrated by the action of acid. An experienced shipwright gave it as his opinion that had the keel been made of elm the iron would have remained sound.

Elm was used in earlier days for water pipes, and only quite recently such pipes were taken up in

Tottenham Court Road and Euston Road, London, and found to be perfectly sound, although they had been in use for more than a hundred years. Some of the actual pipes were exhibited at the Royal Institution a few years since.

Immense quantities have been absorbed for boxes for tinplates, and for seats of chairs and benches, for which elm is admirable. It is used by barge-builders, wheelwrights and for the making of boxes and wagons.

According to Boulger :

> "Gerard tells us that formerly longbows were made from the wood of this species, and its tough bark was made into ropes."

Both the Dutch and wych elm are highly esteemed for boat boards, the latter being preferred. It is used extensively for rubbing pieces for the sides of wharves and piers, where its tough grain provides resistance to blows, and its durability under water is exceptional ; for the wooden walls of farm buildings, and houses, and has been employed for floorings, but its use for the last-named cannot be recommended. Formerly it was used for chests and partitions for storing all kinds of farm produce and utensils ; and for steps and staircases in buildings of all kinds, but for this use it has fallen into disrepute, as the wood will expand and contract with the changes of atmosphere, and is liable to the attack of fungus and beetle. In country places it has been used for pews and seatings in churches, but is generally found severely damaged by lyctus and zestobium beetles.

Throughout Austria and Hungary it has been largely employed for interior house decoration of all kinds, and held there in great esteem. Of late years it has been in demand for high-class work in panelling, etc., in London and elsewhere, being specified by well-known architects. It is doubtful whether the high cost of manufacture, the difficulties arising in seasoning, and its uncertain behaviour after completion, warrant its continued use. In this direction the wood of the Dutch elm was found more satisfactory than of either wych or common elm, both the latter giving trouble.

Elm burrs, carefully selected, as many are too faulty for use, have provided, nevertheless, a limited quantity of most attractive specimens for ornamental woodwork, and a good elm burr will compare favourably for such work with any other kind of wood which can be employed. Elwes mentions many notable examples, and during the last twenty years elm burrs have been in great demand and have commanded high values. Probably the greatest quantity absorbed in one effort was the decorative woodwork for the S.S. *Queen Mary*, where hundreds of flush doors were faced with elm burr, also the dado panelling of the main staircase, the panelling of the main hall and the writing rooms. Some of these burrs were exceptionally fine, the colour varying from a golden to a deep reddish-brown, but always attractive. Whereas in general the work stood well, a certain number of the flush doors cracked and blistered. The very unusual strain on any wood subject to the changes of atmosphere and climate of a sea voyage, and especially that of the Atlantic, suggests that an elm burr which has been found to stand wear and tear in the ordinary way is scarcely the best medium to be employed for ocean-going ships.

A Frenchman, Bernard Palissy, in the sixteenth century, said :

> "I have often wished to make a list of the arts which would cease if there was no longer any wood, but when I had written down a large number of them, I found there would be no end to the enumeration, and, after due consideration, I came to the conclusion that there was not even one trade which could be carried on without wood."

Fortified by the Act of Parliament which made it a capital offence to cut a tree down, confirmed by Elizabeth in the sixteenth century, for nearly two hundred years planting of trees was encouraged and practised throughout the country. Science applied to forestry was not thought of, nor were scientific methods employed. Can we rise to the occasion recognizing to the full the disastrous consequences of delay, following scientific methods and instituting and carrying on a wide embracing measure of re afforestation ?

G. M. Trevelyan has said :

> "In matters of amenity (the) Government in our island is by long tradition heartless and witless. In old days this did not matter, because then landlords were able to beautify the country-side with country houses, parks avenues, gardens, well-kept agricultural estates, and above all with plantations or old English forest trees". . . a they seldom will today.

and further :

> "It (the Government) should charge itself with a generous policy of planting the slow-ripening forest tree of England. The State will still be there in time to com to enjoy their financial value, and the English people will still be there to enjoy their beauty. The Government ought to charge the Forestry Commission with thi policy on a large scale."

Those of our legislators who reach a position o power over the destiny of the country shoul recognize the alarming situation. England with out her woodlands could no longer maintain her people.

It is a curious thing that although the planting and care of trees is little thought of, our people—men, women and often children—have always displayed the utmost interest, and even a possessiv attitude towards the old trees which have bee familiar to them from their youth upwards : the former of these two strange characteristics has no doubt insensibly continued from the time when the British were tree worshippers and practised only the religion of the Druids. The latter, however, should be more seriously considered, because it is evidenc of a valuable instinct which wiser Governments migh have seen and fostered. Illustrating the foregoing an elm tree in a village in Hertfordshire displaye a large burr which the Lord of the Manor sold When the men came to fell the tree the villager prevented them. By order of the Lord of the Mano the men returned in the small hours of the morning whereupon the villagers set the tree on fire an destroyed it, rather than their cherished tree shoul pass into the hands of a stranger.

Since the time of Evelyn (*circa* 1660) successiv Governments, while neglecting the subject of forestry have continued to tax more and more heavily thos few owners of woodlands, without the least regar to the well-being of the community. A contrar policy, wisely followed, even had it only been adopte throughout the last fifty years, would by now hav provided a revenue for the remission of taxatio instead of increasing the already heavy burden.

ORGANIZATION OF SCIENTIFIC AND INDUSTRIAL RESEARCH IN INDIA

TWO articles on the Government organization of scientific and industrial research in India appear n the July issue of *Science and Culture*. One of these escribes the present organization, which now comrises the Board of Scientific and Industrial Research, he Council of Scientific and Industrial Research, the ndustrial Research Utilization Council and the Comittee for the Publication of a Dictionary of Raw Materials. The Council is the supreme body, the oard having now been reduced to the position of n advisory body for scrutinizing schemes of scientific search. A large number of sub-committees are ppointed from time to time to act as auxiliary dvisory sub-committees to the Board and Council, hile the Industrial Research Utilization Council dvises on the utilization by the industries of searches completed by the Board. The Board mainins a research laboratory which was transferred to elhi in 1942.

The article, in a critical review, directs attention the defects of the present organization, notably e overlapping in the functions of the officers and e absence of co-ordination, the complicated produre for dealing with research schemes and prosals, and the absence of any continuous programme f research and of a national laboratory. The writer f the article contrasts the development of the rganization with that of the Department of Scientific d Industrial Research in Great Britain, drawing eely on an article marking the twenty-fifth anniverry of the Department which appeared in NATURE of ay 11, 1940, and stresses the importance of adinistration being in the hands of professional ientific men, of enlisting the active co-operation of scientific talent in the country, of establishing merous research laboratories for the study of subts of national importance which cannot be carried t in the university laboratories, and of encouraging searches in pure sciences and raising a large search personnel by the establishment of many search fellowships and stipends under university ofessors.

The second article outlines proposals for reform. Department of Scientific and Industrial Research, th the status and rank of an "Attached Departnt" to the Commerce Department of the Governnt of India, should be constituted. The principal ecutive officer should be a full-time secretary who ould be a senior scientific man with administrative ilities and a good record in scientific research. The uncil of Scientific and Industrial Research should the parent body, and its functions should be to y down broad features of policy, receive grants m the Government and consider the reports of the ientific and Industrial Advisory Boards. It should courage and promote scientific and industrial search, suggest measures for the development of riculture and industries, and promote scientific rks of national importance. The Council should assisted by two principal advisory boards, taking places of the present Board of Scientific and dustrial Research and the Industrial Research ilization Council, respectively. The Scientific visory Board should have a distinguished nonicial scientific man as chairman and members awn from eminent men of science representing different sciences, and should be the principal body for supervising and laying down programmes for scientific and industrial research, with a scientific man as full-time secretary.

The present research committees should be reorganized, with separate secretaries, and should prepare the programmes of research in their respective fields for the guidance of the Scientific Advisory Board. The research institutes should be under the direct supervision of the Department, and the directors of research would be directly responsible to the Council and act as secretaries of the respective governing bodies of their Institutes. The Industrial Advisory Board should be the main body for advising on all matters concerning the utilization of researches, establishment of new industries, etc., with a non-official industrialist as chairman and an industrial economist as secretary. The Industrial Exploratory Committees should be under the Industrial Advisory Board. There should be a board of assessors for sanctioning the work of the various bodies and laboratories under the Department with a membership of industrialists, scientific men, representatives of Government Departments concerned and some members of the Legislature.

CONTROL OF THE INSECT ENEMIES OF LAC

IT is estimated that insect enemies destroy about 40 per cent of the total lac crop in India every year. The importance of this feature is all the greater for the reason that the people affected by the loss are mainly the poorest cultivators of the country. The chief insect enemies are predators and parasites: the first-named include the larvæ of two species of moths and the parasites are represented by more than eight species of Chalcid wasps. There are three general methods of controlling such enemies—biological, cultural and artificial controls. The principle of biological control has not so far been adequately investigated as regards the lac insect. Cultural methods, although useful, have greater limitations. Artificial methods, on the other hand, are valuable either independently or in conjunction with either of the other two methods. With regard to artificial control, fumigation is a well-known and efficient means, but it is not possible for the Indian cultivators to resort to it unless properly organized fumigation centres are maintained by an outside authority in every village or group of villages. The other method of artificial control is water-immersion.

This subject is discussed by P. S. Negi in Bulletin No. 50 (1942) of the Indian Lac Research Institute. The advantage of this means of control is its ease of application, involving practically no extra expense. It requires only water for immersion and sunshine for the subsequent drying of the lac. It is recommended that the shoots bearing the lac be submerged to a depth of at least two feet for a period of three days either in running water or in stagnant pools This procedure prevents a large number of insect enemies emerging from the lac when stored. The lac is, moreover, more easily scraped from the twigs after such immersion. Shellac manufacture, and physical as well as chemical tests, show that the yield and properties of shellac are not adversely affected by the water-immersion.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 29

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. H. A. Cox: "Timber—Uses New and Old" (Cantor Lectures, 2).

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at Austrian Centre Swiss Cottage, 69 Eton Avenue, Hampstead, London, N.W.3), at 7.15 p.m.—Mr. John F. Shipley: "The Role of Meteorology in Engineering Enterprise".

Tuesday, November 30

INSTITUTION OF CIVIL ENGINEERS (STRUCTURAL AND BUILDING ENGINEERING DIVISION) (at Great George Street, Westminster, London, S.W.1), at 5 p.m.—Dr. Oscar Faber: "Difficulties Encountered and Overcome in connexion with Constructional Works".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. J. C. Drummond: "Food Problems of the Post-War Years", 2: "Food Research".*

Wednesday, December 1

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mrs. Goldsworthy: "Education To-day and To-morrow", 2: "Nursery and Infant Schools".

SOCIETY OF CHEMICAL INDUSTRY (FOOD GROUP) (joint meeting with the SOCIETY OF PUBLIC ANALYSTS) (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 2.30 p.m.—Dr. J. C. Drummond, Dr. H. E. Cox and Dr. E. B. Hughes: "Nutrition of the Public and Food Legislation".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Scientific Papers.

INSTITUTION OF ELECTRICAL ENGINEERS (WIRELESS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. T. S. Littler: "Electrical Hearing Aids"; Mr. C. M. R. Balbi: "A Basis for the Prediction of Performance of Hearing Aids".

Thursday, December 2

BRITISH SOCIETY FOR INTERNATIONAL BIBLIOGRAPHY (at the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 2.15 p.m.—Symposium on "Film Classification, Conservation and Projection".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Prof. W. Perceval Yeats: "Links between Ancient China and the West: a Study of Exchanges in Material Culture", 2: "Ancient Commerce with the West".*

CHEMICAL SOCIETY (joint meeting with the UNIVERSITY COLLEGE PHYSICAL AND CHEMICAL SOCIETY) (in the Chemistry Lecture Theatre, University College, University Park, Nottingham), at 4 p.m.—Dr. H. J. Emeleus: "Some Properties and Reactions of Anhydrous Hydrofluoric Acid".

Friday, December 3

ASSOCIATION OF APPLIED BIOLOGISTS (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 11.15 a.m.—Discussion on Slugs (to be opened by Mr. K. F. Barnes and Mr. D. C. Thomas).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5 p.m.—Dr. C. C. Paterson, F.R.S.: "Dies from Diamonds and their Use: a Triumph of Technical Precision".

INSTITUTION OF MECHANICAL ENGINEERS (APPLIED MECHANICS GROUP) (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Dr. L. Fox and Dr. R. V. Southwell, F.R.S.: "On the Stresses in Hooks and their Determination by Relaxation Methods".

CHEMICAL SOCIETY (at the Royal Technical College, Glasgow), at 7.15 p.m.—Prof. G. M. Bennett: "Some Aspects of the Formation of Ring Compounds".

Saturday, December 4

GEOLOGISTS' ASSOCIATION (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. Alan Wood: "Basic English and its use in Geology" and "Organs of Reproduction in the *Solenoporaceæ*".

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the SHEFFIELD SOCIETY OF ENGINEERS AND METALLURGISTS and the IRON AND STEEL INSTITUTE) (at the Royal Victoria Station Hotel, Sheffield), at 2.30 p.m.—Discussion on the Fourth Report of the Oxygen Sub-Committee.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

TECHNICAL OFFICER to work in a particular district of the county—The Secretary, Berkshire War Agricultural Executive Committee, 1 Abbot's Walk, Reading (December 3).

EDUCATIONAL PSYCHOLOGIST—The Secretary for Education, Education Offices, York (December 4).

LABORATORY TECHNICIAN FOR THE VETERINARY LABORATORY—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (December 7).

VETERINARY OFFICERS to fill vacancies in Government and other services in New Zealand—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (December 13).

REGIUS PROFESSOR OF ZOOLOGY at Glasgow University—The Priva Secretary, Scottish Office, Fielden House, 10. Great College Stree London, S.W.1 (January 17).

ASSISTANT WORKS MANAGER (AERO-ENGINES) for Royal Air For repairs in India—The Ministry of Labour and National Servic Central (Technical and Scientific) Register, Alexandra House, King way, London, W.C.2 (quoting Reference No. C.1525.A).

PAINT CHEMIST for service in the Army Overseas—The Minist of Labour and National Service, Central (Technical and Scientifi Register, Alexandra House, Kingsway, London, W.C.2 (quoti Reference No. F.1790).

LECTURER (Honours graduate) IN MECHANICAL ENGINEERING, and LECTURER (Honours graduate) IN MATHEMATICS—The Secretar Woolwich Polytechnic, Woolwich, London, S.E.18.

ASSISTANT MASTER (graduate) FOR MATHEMATICS, SCIENCE AN DRAWING, in the Ashton-under-Lyne Junior Technical School f Boys—The Director of Education, 8 Warrington Street, Ashton-unde Lyne, Lancs.

METALWORK INSTRUCTOR—The Principal, South Dorset Technic College, Newstead Road, Weymouth.

SCIENCE GRADUATE (Reading or Swanley preferred) to teach GENER SCIENCE part-time in Day Technical School for Girls and PRODU SUBJECTS to Women's Institutes in area of East Kent—The Princip Technical Institute, Longport Street, Canterbury.

DESIGNER OF VENTILATION EQUIPMENT required by the Admiral —The Ministry of Labour and National Service, Central (Technic and Scientific) Register, Advertising Section, Alexandra House, King way, London, W.C.2 (quoting Reference No. C.1874A).

RESEARCH AND THE UNIVERSITIES IN RECONSTRUCTION

THE importance of scientific research as a basis for the industrial reconstruction, adjustment and developments which Great Britain must be prepared to make after the War has been repeatedly emphasized in recent months. Following on Sir Harold Hartley's appeal for industrialists to become more research-minded, Lord McGowan discussed the particular position of the chemical industry in an address before a joint meeting of the Institution of Chemical Engineers and the Chemical Engineering Group and the London Section of the Society of Chemical Industry. The report of a committee of the Federation of British Industries under the chairmanship of Sir William Larke, to which Dr. Dunsheath referred in his Atkinson Memorial Lecture to the Royal Society of Arts earlier this year, has now been published, following swiftly on another notable report from the Parliamentary and Scientific Committee.

The burden of this consensus of opinion is the imperative need of a very considerable expansion of scientific research, both within and without industry, if a policy of full employment is to be pursued, our material resources effectively and efficiently utilized in a rising standard of living and the essential export trade maintained, restored or expanded. On the extent or nature of that expansion there may well be differing opinions, and the reports in question and Lord McGowan's paper are concerned more or less deeply with the different aspects of the problems involved.

The expansion of the research effort in Great Britain involves a number of fundamental problems, both of policy and of tactics. First, there is the question of organization, and structure : Are the existing organizations of the right type, do they make effective use of the resources at their disposal and is the distribution of research effort over the whole field balanced ? Secondly, there are the questions concerned with the endowment of research and the best means of providing the essential financial support, and the magnitude of that support required. Thirdly, there are the problems involved in the supply of research workers and other scientific personnel, their training, remuneration, status and the like ; while fourthly, there are the questions concerned with the utilization of the results of research, involving the broad education of both industry in particular and the nation as a whole.

In the main, it may be said that the report of the Federation of British Industries is concerned with the second group of problems. Into the broader questions of the strategy of research, industrial or otherwise, it does not enter, and it passes rather superficially over the third group of problems concerning the supply and training of research workers. One of its principal recommendations, the establishment of a Bureau of Industrial Research, does indeed enter the field of organization and structure, but on that group of problems generally the report expresses satisfaction with the general scheme of organization at present existing, although critical of the policy of the Department of Scientific and Industrial Research as somewhat restrictive. On the other hand, the Committee is far less critical of the research associations than Lord McGowan was, and the general tenor of the report is in striking harmony with Sir Harold Hartley's pamphlet.

The report of the Parliamentary and Scientific Committee, however, on "Scientific Research and the Universities in Post-War Britain", has a freshness of outlook and a pertinence in relation to demobilization, post-war planning and educational reform which make it of first-class importance. In this respect the second part of the report, on the supply and training of research personnel, almost completely outshadows the first part on the need for increased research. The latter is an able re-statement of the case outlined by Sir Harold Hartley, though covering the whole field of scientific research, including agricultural and medical research as well as industrial, with a welcome emphasis on the need for biological research in all its branches.

While this statement is the nearest approach to a review of the whole front of research and a challenge for more balanced development and distribution, a question to which the Committee proposes to return in a future report, the second part of the report is an acute analysis of problems which have indeed been touched upon of late—for example, the House of Lords' debates on July 15 and 20—but have not received anything like the emphasis they merit. They hold as essential a place in any scheme for educational reform as they must do in any plans for demobilization.

To enable research work to be adapted and expanded to the peace-time requirements, there must be an equivalent adaptation and expansion of the present supply of scientific personnel. For this supply there are two sources: existing scientific workers released from temporary war-time employment, the Services and armament work, and trained, as necessary, for new peace-time research requirements; and increased output of science graduates from the universities and technical colleges. The sum which can be profitably expended on research is strictly limited by the number of inspired leaders and of trained workers available. The provision of sufficient numbers of the right men with the right training is the first essential in any extension of research.

It is obvious that such expansion of the supply of scientific personnel involves expansion at the universities and technical colleges, and an all-round improvement in the teaching of science and scientific principles at all stages of education for the whole school population of the country. First in urgency in the Committee's view is the need for the effective organization of the demobilization of the large number of scientific people now on war work or in the Services, to enable them to complete their training and to guide them into positions where their previous training and their war experience will be of special value. A systematic approach covering the whole of British industry is a matter of real urgency if we are to ensure that full use is made of the considerable reserve of scientific intelligence available in the technical branches of the Armed Forces and the Supply Departments. The Committee hopes that this will be adequately covered by the special Committee under Lord Hankey dealing with such matters, but emphasizes the necessity of considerable funds if the objective is to be realized without serious loss of time.

Owing to the foresight of Lord Hankey and the committee responsible for the preliminary training of the younger of these men, many of them have had substantial, though incomplete, university training in physics, chemistry, engineering, etc., though no in the biological subjects, and should be able to complete a broad course of education within one o two years. The Government has already recognized the importance of such men in the post-war effor and, as indicated in the White Paper on Educational Reconstruction, has initiated a scheme by which they will receive training grants on demobilization Others, however, such as those who have entered the Forces immediately on qualification, may well requir similar grants for refresher courses, as is well argue by Mr. E. S. Conway in "Post-War Employment"* Mr. Conway is concerned with the maintenance o high standards of professional qualification, and his suggestion that professionally trained and experienced ex-service men who, as a result of war service, hav lost touch with their work, should be allowed the right to qualify in a shorter period and at a lowe standard of attainment, providing they follow "post-completion course" over a period of year which would bring them up to a standard in advanc of that normally required but in a more specialize field selected by the individual concerned, deserve consideration by professional bodies as well as b Lord Hankey's committee.

This whole passage, with its warning against th intellectual stagnation that tended to creep into th professions between 1919 and 1939, owing to th lowering of standards, and, not least, its reminde that the healthiest incentive to research is a natura enthusiasm for the work, deserves the serious attention of all scientific workers. Some may well hold that Mr. Conway goes too far in the measures o compulsion he advocates. None the less, scientifi workers will neglect at their own peril this clea warning of dangers ahead.

The value of such measures in bringing our scientific resources in personnel to maximum efficienc cannot be denied, but for the training and provisio of research workers we must continue in the main to look to the universities. To deal with a rapi growth in the number of students of science an technology is one of the first reasons for the expansion of existing universities, and possibly the development of some existing institutions into universitie The Parliamentary and Scientific Committee, pointin out that we have more than doubled the output engineers and physicists during the War, estimate hat the universities of Britain will require to handle ltimately some two to three times the 1938–39 umber of students of science and technology in rder to meet the requirements of any thoroughoing post-war reorganization of research and techical development in respect of trained personnel, part from further developments foreshadowed in onnexion with science teaching in schools.

---

* "Post-War Employment." By E. S. Conway. Pp. 142. (Londo Jonathan Cape, Ltd.) 8*s*. 6*d*. net.

Lord McGowan, in the address already mentioned, ubmitted that the main function of the universities to train and supply the community with the best ype of research worker, but if the post-war requireents are to be met quantitatively as well as qualitavely, the urgency of the problem cannot well be ver-stressed. The Parliamentary and Scientific ommittee regards a permanent increase in the udent population of Great Britain as a national ecessity. It is not too soon, it urges, to consider e requirements of 1950. Any such programme early involves the provision of academic staff as ell as buildings and equipment, and the necessary rovision must be made in good time. Taking first e question of staff, an increase in university staffs well as stipends is recommended. Men of ability ust be recruited as they are released from their resent posts, and the present low scale of university ipends must be revised if the right men are to be tracted and retained—a point which has been reiterted in the House of Lords debates and in Mr. Bruce ruscot's book "Redbrick University" and elsehere.

If the necessary staff is to be available to cope with e immediate post-war demands, the conclusion ems inescapable that there must be priority of emobilization for university teachers from Governent service. In this conclusion the Parliamentary d Scientific Committee appears to controvert the rinciples of demobilization already laid down by e Government. The principle of demobilization cording to length of service is, however, clearly of lue only as a general guide, and in this respect the port by implication emphasizes the necessity of orking out a really scientific scheme in which due rovision is made for the demobilization at the earliest ssible moment, irrespective of length of service, those workers who are essential to the progress the general measures of reconstruction. Unless is is done, we may well find that men anxious to -train or to complete their training at a university technical college are unable to do so because the achers required have not been released ; this state affairs would frustrate the policy of full employent from the start.

What is essential, however, is that this position d the exceptions that it may be necessary to make the length of service principle shall be fully and ficially explained in advance, and that full assurance given that the exceptions to be made are deterined solely by the public and general interest. here must be no room for any suspicion that private sectional interests are allowed to influence policy. hat point is well made both by the Sub-Committee the Conservative Party on Demobilization and e-settlement in its first interim report recommending a points scheme, and in a statement by the Tory Reform Committee. No plan for demobilization, however well devised, will succeed unless its nature and objects are fully understood by all concerned, and it must be explained to them now.

Besides staff, materials and finance must be made available for the expansion of research schools in the universities, and the Parliamentary and Scientific Committee estimates that a capital sum of £10,000,000 will be required for buildings and equipment, including libraries, spread over the first five post-war years, as well as adequate priority for the work and materials involved. In addition, the present annual Treasury grant to the universities of about £2,250,000 should be increased to six or seven millions.

The Committee assumes that the University Grants Committee will shortly be considering the immediate needs of the universities of Britain, both as to capital expenditure and income, to enable them adequately to carry out the vitally important duties which they will be called upon to undertake when demobilization begins. The Committee doubts, however, whether the University Grants Committee, as at present constituted, has either the powers or the machinery for initiating the major changes now required. Its present constitution excludes membership of those actually engaged in university work, and it is without any representatives of the 'users' either of university-trained personnel or of the results of university research. It can represent to the Treasury the case for expansion and recommend allocation of the funds available, but it lacks any power to consider University policy as a whole or to advise the creation of new chairs, new departments or new universities. No doubt these points will be considered in the re-organization of the University Grants Committee now contemplated (see NATURE, November 20, p. 595).

While the University Grants Committee is likely to consult industry and the professional institutions, and there is no reason to suppose that its findings will lack boldness, there is a strong case for some change in organization. The Parliamentary and Scientific Committee, like Lord McGowan, emphasizes the vital necessity of preserving the present freedom which the universities enjoy from control by the Board of Education or other Government Departments, but if the universities are to ensure the best use of the increased assistance from the State, or from industry, for which Lord McGowan pleads, some further means of co-operation with industry must be developed. The Parliamentary and Scientific Committee suggests accordingly that the universities should establish an effective advisory council which would be able to effect co-ordination and eliminate any unnecessary or wasteful overlapping.

Suggestions have from time to time been advanced that particular universities in Britain should concentrate on special fields of training. Mr. Bruce Truscot, for example, suggests that by inter-university arrangements most of the schools which have few or no students could be eliminated and the teaching concentrated where it best fits into the general programme. The financial gain would be considerable and the gain in general efficiency still more. The point is again made by the Parliamentary and Scientific Committee, which suggests that a general survey may well be needed to ensure efficiency all round.

In the unofficial Committee of Vice-Chancellors and Principals, British universities already possess the nucleus of a central advisory body which might discharge such responsibilities. The representation should include, however, the teaching staff of the universities and persons of distinction in industry, medicine, agriculture, education, the Government services, etc., in which university graduates are employed. A single body of this kind would be too large and unwieldy for efficient operation, and formation from it of a smaller university council, with sub-committees to deal with special interests, is suggested. Set up by the universities themselves in consultation with the other interests concerned, this council would in no way encroach on the essential freedom, diversity, integrity or independence of the universities. By ensuring that these essential privileges are not endangered by any charges of waste, inefficiency or confusion, it would provide the most effective answer to those who contend that there can be no substantial increase of university grants without introducing some measure of Government control.

An even closer analysis of this aspect of university finance is to be found in the report on university finance in Great Britain issued by the Committee on Post-War University Education of the British Association. This report is more complacent with regard to the University Grants Committee than is that of the Parliamentary and Scientific Committee, and no change in organization is suggested. The first step recommended is that the University Grants Committee should ask the universities to forecast their immediate requirements on the basis of 1938 prices and a fifty per cent increase in numbers. The question of control by the State is recognized, but the tribute to the past work of the University Grants Committee and the confidence that the universities will be strong enough to resist any harmful pressure which might be coupled with substantial increases in State grants are accompanied by a reminder that, while the universities safeguard their autonomy, they must overcome their fear of Government influence in university affairs.

On the whole, the British Association Committee's report, at least qualitatively, underlines the same points as that of the Parliamentary and Scientific Committee. It has less to say about research, but points to the increasing expense of the equipment required for that purpose, and comments on the inadequacy of many laboratories and the piecemeal and unbalanced development due to the frequent dependence on the whim of individuals and the immediate needs of the more enlightened industrial organizations and associations. Far more attention must be paid to the exploration of new fields of knowledge, and in particular the report suggests that the experience of the War and the numerous schemes under discussion for extending the application of science to the whole field of social and industri reconstruction should be decisive arguments in favou of greater State financial support of the maj university objectives. The importance of the co tribution which the universities of Great Britain ca make in training research workers is again emphasize in this connexion.

With regard to finance, the report considers th the universities must look in the immediate futu to State and local assistance for their major develo ment, and it is urged that the Treasury grant shou be at once doubled after the War. Local authoritie grants should also be increased. Most of these ha remained unchanged for some years, whereas rateab values have increased and the services of the unive sities to their localities have extended; but the may be some need for further change in universit organization if increase of such local grants is n to be accompanied by undesirable increase in loc control.

On the question of capital expenditure, the Britis Association Committee points out that this will be co fined chiefly to buildings, but it is pointed out that such needs would fit well into a public works sche designed to assist ordered demobilization, and, apa from some temporary building to provide lecture an laboratory space for the great influx of students imm diately after the War, would provide Great Britai with permanent assets well worth the expenditu A total expenditure of twenty-five million pounds visualized under this head. On maintenance, th report stresses revision of salaries, which should given priority over almost everything else and the essence of the situation. The salaries of bo lecturers and professors require revision, though different grounds, and the institution of an adequa supply of senior lectureships and readerships strongly urged, as well as an overhaul of the who question of superannuation.

So far we have discussed the situation mainly wi reference to the training of personnel for researc though it has been indicated that the plan for educa tional reconstruction proposed in the Government White Paper necessitates a considerable increase the existing number of teachers. A further Britis Association's Committee report puts the shortage more than 120,000 rather than the official estimate 70,000, and the majority of these will require university degree course followed by a two-yea training course afterwards. This is obviously important factor in determining the expansion of th universities, and also has a bearing on the trainin and supply of laboratory technicians, who are no le important in the development of research depar ments than the supply of research workers themselve The Parliamentary and Scientific Committee stress the importance of developing technical educatio and welcomes the assurance in the White Paper wi regard to the association of the technical colleges a art schools with the industrial and commercial li of the country. Experience, it is pointed out, sho that one graduate research worker can, on average, usefully employ at least three laborato technicians.

There is yet a further matter of vital importance to he supply of trained personnel. The Parliamentary nd Scientific Committee urges that State bursaries nd engineering cadetships should be continued fter the War ends, and developed to cover sciences ot hitherto included. Greater aid should be availble for young graduates who wish to continue tudies for a higher degree and who could at the same ime assist and gain useful experience in demontrating. In addition to generously implementing he recommendations of the Norwood Committee, he dearth of postgraduate scholarships and of postoctoral fellowships requires attention. The present nadequate grants of the Department of Scientific and ndustrial Research should be increased both in umber and in value, and the medical and agriculural sciences should similarly be provided for through he Medical and the Agricultural Research Councils. inally, larger assistance to young people in industry enable them to take full-time courses is essential we are to produce the men who have a fundamental nderstanding of processes as well as the much greater umber of those who know how to work the levers nd supervise the repairs.

This widespread measure of agreement on the eans by which Great Britain is to be assured of an dequate supply of trained personnel for all branches f scientific research follows on a growing recognition at the conditions of service in both industry and e universities must be such as to attract men of e highest quality. It received expression in the ouse of Lords debate and notably in Lord McGowan's eech then and his subsequent address already ted. It is recognized in the report of the Federaon of British Industries, which also advocates a ore general provision by industry of funds for llowships, bursaries and the like at universities nd technical colleges and schools. The report of e Parliamentary and Scientific Committee and ose of the British Association committee are calcuted powerfully to assist the task of educating public pinion to the necessity of early and effective action. he case could scarcely be put better. Even if we take e maximum amounts proposed—increase of the nual Treasury grant to the universities to six or ven million pounds and of £25,000,000 for capital xpenditure—the proposals are moderate in relation the issues involved or in comparison with, for xample, expenditure in the United States. Even ore clearly the need for immediate action is made anifest, and this action must form an integral part the plans and machinery for demobilization and the post-war building and public works schemes. ot only have those plans to be formulated; they ve also to be explained in advance.

The reports which have been referred to above dicate the ground to be covered and demonstrate nphatically the dangers of the Government's dilariness in taking its decisions and formulating policy er the whole field of reconstruction. They attest ce more that transition from war to peace economy ust be a continuous process, planned and ordered d explained in advance, if frustration and confusion e not once again to follow the cessation of hostilities.

THE WRITING OF ENGLISH

The Reader Over Your Shoulder

A Handbook for Writers of English Prose. By Robert Graves and Alan Hodge. Pp. 446. (London: Jonathan Cape, Ltd., 1943.) 18*s*. net.

MANNER of speaking or writing is often an indication of a person's mental make-up, and, as a modern writer has asserted, faults of style may reflect faults of character. At any rate in the world of to-day, ability to express oneself well in speech and script is a most useful quality; and it is a quality that can be taught to, and learnt by, most people, if they take the necessary pains. The trouble with most poor writers is that they are lazy: they lack the 'passion to excel' of the artist and the craftsman. The technical writer, in particular, is often so keen to communicate his knowledge, to 'get there', that he does not worry about style or method of presentation, and therefore is put down as an unlettered man; whereas by taking thought and a little trouble, he could greatly improve his style and 'put it over' far more satisfactorily.

Of the factors that make for good prose composition, perhaps the chief is having something to say; but that is run very close by being able to say it clearly, precisely and concisely. Clarity is fundamental, and it is achieved not only by thinking clearly, but also by knowing the exact meanings of words, by ability to choose the *mot juste*, and by the more technical procedure of arranging words, sentences and paragraphs in logical order. "Style is connexion", said Jowett, "art is putting things in their places". Balance and rhythm are also valuable qualities.

Messrs. Robert Graves and Alan Hodge, in their interesting book, assert that it is impossible to write perfect English, and even to write it well is difficult. Few will controvert this statement, especially those whose efforts to succeed have been made with toil and sweat and, perchance, with tears.

The rules of good writing apply equally well to authors of scientific and technical prose as to purely literary authors; but there is an important difference between the two kinds of writing. Both aim at imparting information, but the literary man relies to a considerable extent on emotive appeal, with which the scientific writer is not concerned; the latter's job is to make exact statements about facts and hypotheses. Not that some scientific writing is entirely without emotive appeal, for example, astronomy and biology, which often excite wonder, curiosity and humility, but that is usually quite a secondary consideration.

The book under review is divided into two parts. Part 1 deals with the peculiar qualities of English, its origin and its history; and then with twenty-five principles of clear statement and sixteen principles of the graces of prose. Part 2 consists of detailed criticisms of faulty passages from the writings of many eminent modern authors.

The peculiar qualities of English, which are due largely to its hybrid origin, include richness in words and metaphors, absence of gender and inflexions, interchangeability of certain parts of speech, wide choice of prefixes and suffixes, and wealth of prepositions, all tending to make it flexible and expressive of subtle shades of meaning. But they also make the language easy to abuse, and, together with its inconsistent spelling and pronunciation, make it difficult to learn.

As causes of the present confusion of English prose, the authors postulate haste, distraction and dividedness of mind, timidity and modesty. The ragged conversational style used by prominent people, they say, would in the 'eighties have been attributed to drink, mental decay, or vicious upbringing! This circumstance and the habit of dictating to a typist are responsible for much clumsy composition. Dividedness of mind and timidity are characteristics of 'official' English, including that of Cabinet Ministers who do not see eye-to-eye with their colleagues, that of priests who are assailed by honest doubt, and that of Communists uneasily following the party-line.

Where is good English to be found? they ask. Not among those who might be expected to write well professionally, such as schoolmasters, the clergy, men of letters, and trained journalists; but rather among those without literary pretensions who have responsible executive jobs in which the use of official English is not compulsory. Official English comes under the authors' ban, but they plead justification of it for use in framing Bills and Regulations, for these have to pass currency in courts of law.

Chapters follow on the beginnings of English prose, on the ornate and plain styles, and on the various kinds of prose—classical, romantic and recent. Then come the principles of clear statement and of the graces of prose, which are too numerous to be detailed here; it must suffice to single out a few.

There should never be any doubt concerning the 'who', the 'what', the 'when', the 'where', the 'how much', the 'how many', and the 'how long'. (The authors are especially critical of the ambiguous use of 'we'.) Every unfamiliar concept should be clearly defined, and neither discussed as if the reader knew all about it nor stylistically disguised. No unintentional contrast between two ideas should be allowed to suggest itself. (Example: "On entering the Guildhall, Mr. Lloyd George was enthusiastically cheered, while Lord Oxford was accorded a great ovation".) Critical readers of scientific and technical literature are well aware of the misuse and more often the complete omission of hyphens (the latter largely through laziness). The object of hyphens is to make the sense clear and the reading easy. In the authors' example: "In the Southern States slave-owners of property were expected to give their masters a proportion of its yield", slave-owners should be 'slave owners', that is, slaves who were owners of property. Punctuation should be consistent and denote quality of connexion rather than length of pause. Over-emphasis of the illogical sort tolerated in conversation should be avoided. Example: "That food is more important in the preservation of health than housing was shown by the late Dr. M'Gonigle at B——, but this is by no means to say that housing is not of the first importance". Authors' comment: "If food is more important than housing, housing cannot be of the first importance".

The principles of graceful writing relate to sensibility rather than to sense; three of them are concerned with metaphors. These should not be mismated; or piled on top of one another; or used in too close association with unmetaphorical language (for example, "Kay Rimmer sat with her head in her hands and her eyes on the floor"). The descriptive title of a person or thing should not be varied merely for the sake of elegance.

A fault that is frequently found in scientific papers, as well as elsewhere, is to repeat the same word too often in the same sentence or paragraph. The authors give these examples *inter alia*: "There has been . . an honest dread on the part of many of the popularization of a form of godliness that lacked its power of the substitution of an emotional appeal at the fireside for the organized fellowship . . ." Similarly with the preposition 'in': "In fact, in countless villages in England in this war and in a variety of ways, there has been a most astonishing adaptation of local products to war needs". Another blemish is to place too close together words which rhyme or form a jingle: "The need of registration or re-registration at this station of all workers on probation is to be the subject of examination by the Administration' —perhaps rather an extreme example. The comparative and superlative of adjectives are sometime used where there is no degree of comparison; fo example, "The new inquisitions are more omnipresent than the old". There are no degrees o omnipresence. Over-emphasis by the illegitimate us of adverbs like 'infinitely' and 'immeasurably' is also to be avoided: "Buildings . . . have been physically knocked down". It would be difficult to knock them down mentally or morally. Irrelevancy and verbosity are common characteristics, more especially at scientific meetings, where such statements as "There is another observation I would like to make befor I pass on", and "We must use our best endeavours (that is, try hard) are frequently heard. In his "Scienc and the Modern World", Prof. Whitehead wrote: "The inevitableness of destiny can only be illustrated in terms of human life by incidents which in fac involve unhappiness". Since, say the authors, destiny is by definition inevitable, the sentence can be reduce to "Human destiny can be exemplified only wit unhappy instances".

These numerous principles (which in their wealt of negative injunctions remind one of the Decalogue are then used as criteria to assess the literary valu of many passages from modern literature; and mainly with destructive effect. Politicians, novelist literary critics, journalists, economists, soldier sailors, philosophers and men of science, all ar 'hauled over the coals' for transgressing one or mor of them. Many of the criticisms are, in the reviewer opinion, 'pernickety'; the passages quoted are in most cases clear enough in meaning, and if one set out to write, bearing in mind all the author numerous 'don'ts', one would not get very far: th product would be 'sticky' and lack spirit. On th other hand, it must be admitted that almost withou exception the 'fair copies' given by the authors ar superior to the originals: they are clearer, mor exact, and frequently more concise. A few example taken from scientific literature must suffice.

Sir Arthur Eddington, in "The Expanding Un verse" (1932), wrote: "The position with regard t the thermodynamical running-down of the univers has not materially altered since I discussed it for years ago". The authors say that, literally, th means that the universe has not run down muc during the past four years! Their fair copy runs "My theory, published four years ago, about th thermodynamical running down of the universe ha not since been seriously questioned". Althoug circumlocutions, like 'the position with regard to were placed on the Index Expurgatorius by S Quiller Couch many years ago, and the author version is shorter, very few readers would interpr the passage in the extreme way suggested by them On the other hand, few will controvert their remar that ". . . the theory of cosmic rays is being urged in this connection . . ." is a cumbersome way of saying "the theory of cosmic rays mentioned".

Dr. Julian Huxley is reprimanded for having written ". . . the economic and social forces have taken the bit in their teeth and threaten to pull the fabric of civilization down if not harnessed and conrolled". The authors point out that an animal which takes the bit between its teeth and threatens o pull down the fabric of a building must be already harnessed to it; and that it is difficult to imagine a context in which horses or mules taking the bit in their teeth threaten to pull down the fabric of a building. The fair copy runs ". . . forces generated by the interaction of new economic, industrial, military and other systems may now disrupt civilizaion".

Sir James Jeans is taken to task some sixteen times for various alleged minor offences in a passage of about 150 words taken from his "The Stars and heir Courses" (1931). *Inter alia*, he is accused of unnecessary repetition and of disguising it by contant variation of language. According to the authors, "nearly all scientists, at the point where they turn rom mathematical or chemical language to English, eem to be relieved of any further obligation to precise terminology": a statement that is probably meant to refer to popular scientific writing.

It would be wrong to infer that the authors show ny particular bias against scientific authors. They o not. They level their shafts indiscriminately gainst all writers who, in moments of temptation or berration, sin against the light emanating from their orty-one commandments. Everyone who wishes to rite well has something to learn from a perusal of his interesting book, whether he be a literary man, man of science, or a common scribe.

E. H. Tripp.

RESOURCES OF THE SEA

he Fish Gate

y Michael Graham. Pp. 196+16 plates. (London: Faber and Faber, Ltd., 1943.) 10*s*. 6*d*. net.

N the great experiments which made Robert Boyle the 'father of chemistry', we find him saying, very now and then, that his purpose was "the mprovement of Knowledge, and not of Trade", or ther words to that effect; for he knew that "both cholars and Gentlemen are wont to look upon the nquiry into Manufactures as a *Mechanick* employment, and consequently below them". After two undred and fifty years we have changed our minds, nd come to see that science must pay its way, and tand or fall, like all other occupations, by the measure of its usefulness to mankind. It has been omewhat hard to learn this lesson, and to trim our ourse to the new concept of 'science'; but we have plain example in the study of the sea, where many ciences meet together, and do so (if you only leave hem alone) to the benefit of all who do their business the great waters. How this happens is told by Michael Graham in "The Fish Gate", with ample nowledge, industrial and scientific, of the fisheries, ith many beautiful illustrations, and with a literary aste and skill which touch art, from the title-page the end of the book.

The industrial revolution has swept our old fishermen and their boats away; there is not one left in the little towns, like my St. Andrews, where I remember the busy harbour, and the women baiting the lines or mending the nets before their doors. "There are still the small owners", says Michael Graham; but he means the men who "own two or three vessels, which cost about £4,500 apiece when new". It is this modern industry which the author knows by heart which fascinates him, and he describes it to the very life: the pontoon at Grimsby where 500 tons are landed every day, and dispatched to two thousand destinations; the big Hull trawlers following the cod all the way to Novaya Zemlya, making a £2,000 catch in a few hours' fishing, and coming home with their holds half-full lest the market be glutted; the steam-drifters at Smith's Knoll in October, their skippers feeling their way with the echo-sounder, and the sea aboil with the 'swim' of herring, which love the merry moonlight as they have always done.

In these great modern fisheries the catch kept rising, even by leaps and bounds, until a day came when it rose no more. The North Sea alone was yielding 430,000 tons of fish a year thirty years ago—an almost fantastic quantity; twenty years later, with enlarged fleets, more powerful boats, more costly gear, and even a smaller mesh, the annual landings were just *a little less* than before. In short, when the story has been told of enterprise and expansion, of capital invested and fortunes made, there comes the inevitable reaction, a diminution of profits and an undeniable scarcity of fish. Some form of control becomes imperatively necessary, difficult as it may be to enforce it, and yet leave men content and secure. As a first but very considerable beginning, Michael Graham welcomes and applauds the Convention of 1937, which took formal steps towards international regulation of the trawl-mesh; it seems so obvious that if you would have the full-grown fish you must let the little ones go free!

But fish are not like ourselves. The case is not so simple when you deal with creatures which lay a million eggs in order that (normally) one pair may survive and take the places of their parents in the sea; when Nature herself thus slaughters the innocents; and when we know that small plaice and haddock are still plentiful in spite of everything, while the big are all gone and even the middle-sized are scarce indeed. Michael Graham is always candid, and, much as he praises the mesh-regulations, he is ready to concede that they will not suffice of themselves; for sooner or later there must come a self-denying limitation of the actual catch of fish. The coastal waters of the North Pacific teemed with halibut, and the fishery seemed inexhaustible less than forty years ago; but it proved to be nothing of the kind, and presently found itself on the road to ruin. Now a bold and drastic curtailment of the total catch has given a new lease of life to the industry. There is no exception to what Michael Graham calls "the Great Law of Fishing", that *fisheries which are unlimited become unprofitable!* But he has faith and confidence enough to turn the phrase the other way, and say that *limiting the effort will restore profit to a fishery.*

The author touches on every aspect of the fisheries, even, though lightly, on the cookery of fish. But when he tells us that we should fry our cod and boil our herrings, I begin at last to differ from him.

D'Arcy W. Thompson.

Annual Reports on the Progress of Chemistry for 1942

Vol. 39. Pp. xxviii+257. (London: Chemical Society, 1943.) 15*s*.

SINCE it is no longer profitable to attempt to review progress along the whole chemical 'front' in a volume which is meant to be read, these annual reports have been deliberately restricted in scope, whereby surely their appeal has been widened. Each year a number of important topics are selected for detailed discussion, so that representative pictures of progress in various fields of investigation are presented as a kind of 'album'. Paper shortage has on this occasion prevented inclusion of sections on analytical chemistry and on radioactivity and sub-atomic phenomena; but general and physical chemistry, inorganic chemistry, crystallography, organic chemistry and biochemistry are well represented.

G. Gee discusses the physical chemistry of rubber solutions; C. E. H. Bawn deals with the atomic reactions of the alkali metals; and W. F. Berg examines the physical chemistry of latent-image formation in gelatin – silver halide emulsions. H. J. Emeléus's brief review of progress in inorganic chemistry is based on general interest rather than on specialist value. A. L. G. Rees follows with an account of the luminescence of inorganic solids, and A. J. E. Welch illustrates some applications of modern technique in inorganic chemistry. J. M. Robertson's report on crystallography relates to the technique of structure analysis as well as to recent data for certain inorganic and organic structures. Organic chemistry is represented by the following subjects: stereochemistry (M. P. Balfe and J. Kenyon), general methods (F. S. Spring), the lignin problem (E. G. V. Percival), polycyclic aromatic compounds (J. W. Cook) and heterocyclic compounds (T. S. Stevens). Biochemistry is not on this occasion represented by the vitamins; instead, L. J. Harris discusses nutrition with special reference to trace elements, C. G. Anderson reviews the more outstanding developments since 1940 in immunochemistry, J. L. Cranmer and A. Neuberger briefly summarize recent advances relating to the proteolytic enzymes, and F. W. Norris gives an account of recent work on some plant products and enzymes.

Topographical Anatomy of the Dog

By Dr. O. Charnock Bradley. Revised by Prof. Tom Grahame. Fourth edition. Pp. xii+316+9 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1943.) 28*s*. net.

THE contents of this standard book are so well known and clearly indicated in the title that it is not necessary to review them. This edition has been revised by Prof. Tom Grahame and, while the bulk of it remains the same, there has been a certain amount of revision and three noteworthy alterations. First, after the descriptions of most of the muscles, a brief note on the function of each has been appended. Secondly, the number of illustrations has increased from 91 to 128 plus a frontispiece. The frontispiece is that of the skeleton of the dog, the majority of the new text-figures are of bones to illustrate the position of the origins and insertions of the muscles, and the last, accompanied by about three pages of description, is to illustrate the superficial lymph vessels and nodes. Thirdly, the new edition contains nine radiographs well reproduced upon plates. These three additions add materially to the usefulness of the book from the student's point of view. There i perhaps one criticism that can be made of the radiographs and that is, seeing it is the student's firs introduction to these valuable aids, they might b more fully labelled and explained in the accompanying legends.

The whole book reflects considerable credit o editor and producer alike, and, while primaril intended for the veterinarian, it will be found mos useful to anyone interested in comparative anatomy

An Easy Outline of Astronomy

By Dr. M. Davidson. (Thinker's Library, No. 95. Pp. iv+108+2 plates. (London: Watts and Co. Ltd., 1943.) 2*s*. 6*d*. net.

WITH astonishing versatility the Rev. Dr. M Davidson turns from philosophy to give u this little volume on general astronomy. The reade who has no previous acquaintance with the subjec can master the book without mental indigestion, an will leave it with a working knowledge of the element of descriptive astronomy. The author gives an up-to-date account of our knowledge of the movements dimensions, masses and compositions of the heavenl bodies without dealing with the identification of th constellations and individual stars. A few erro have been noted: among those which the studen will find most puzzling are contradictory statement (pp. 55, 56) on the proportion of comets with retrograde motion, and a loose construction (p. 31) whic makes it appear that solar eclipses which are no total are annular. In a section (p. 68) dealing wit the transformation of mass into radiation, D Davidson is betrayed into assuring his readers tha "when we burn a piece of coal, the weight of its ash and the smoke emitted is very nearly the same a the original weight of the coal"—surely a statemen that would make Lavoisier turn in his grave! B these are minor points which do not detract serious from the merits of this authoritative presentatio of the salient facts of astronomy in a form suited t the complete novice. A. H.

Beyond the Microscope

Being an Account of a Voyage of Discovery in th Borderland Country between the 'Living' Organis and the 'Non-living' Chemical. By Kenneth M Smith. (Pelican Books, A.119.) Pp. 12+4 plate (Harmondsworth and New York: Penguin Book Ltd., 1943.) 9*d*. net.

THIS volume covers the whole sphere of vir diseases in plants and animals and their investigation. The structure of viruses is discuss and illustrated by photographs taken by means the electron microscope. Among the chapter hea ings are "Viruses and Tumours" and "Combati the Viruses". The scope is remarkably wide, b the presentation is clear and the book makes mo interesting reading.

Human Physiology

By Kenneth Walker. (Pelican Books, A.102.) P 128+2 plates. (Harmondsworth and New Yor Penguin Books, Ltd., 1943.) 9*d*. net.

THIS is an elementary account of human physi logy for the layman written in simple langua and essentially concerned with the bearing of physi logy on health. Line drawings in the text follow th time-honoured tradition that no book on physiolo should be well illustrated.

THE ROYAL SOCIETY AND ITS HOMES*

By SIR HENRY DALE, G.B.E., PRES.R.S.

THE interest of the Crown in the Royal Society, and perhaps a recognition of a duty to provide commodation for it, were signified by King Charles I's grant of Chelsea College and its estates, as set rth in our third Charter of 1669. The property roved, alas, for various reasons, to be much more burden than an asset, and Christopher Wren, in 382, with the Council's approval and recorded ratitude, sold it back to the King for £1,300. Mean-hile, an opportunity for the Society to acquire a ouse of its own, built to the designs of Hooke and ren, on a piece of land granted by Henry Howard om the grounds of Arundel House, had not become fective. The Society, therefore, remained for fifty ears from its foundation a tenant of rooms in resham College, until in 1710, when Isaac Newton as president, it acquired the house in Crane Court, f Fleet Street, which was its home for another xty-eight years. In 1778, thanks to the personal terest in our affairs of King George III, the friend our great president of those days, Sir Joseph Banks, e Society was granted quarters in Somerset House. herewith the obligation of the State to provide us th housing was for the first time definitely accepted, n generous recognition by the Sovereign of the rvices which science had rendered to the state", as anks stated in his address of 1780. The records show at the accommodation in Somerset House was garded from the first as inadequate, even though r requirements had been reduced by the transfer our "Repository of Rarities" to the British useum. The rooms, on the other hand, can be seen om prints of the period to have had a pleasant gnity, and the Society remained in them for nearly ghty years.

Towards the middle of the nineteenth century, a ovement arose to secure new and better accommo-tion for the Royal Society, and at the same time for e other principal scientific societies then existing the Linnæan, Geological, Astronomical and Chemi-l Societies. So early as 1847 a memorandum was esented to the Council by the newly founded ilosophical Club, a more seriously minded secession om, or rival to, the Royal Society Club of those ys, formed under the same influences as those ich had just carried the revised method of electing r fellows. The Club presented proposals for bringing major scientific societies under one roof, centraliz- and co-ordinating their libraries without any empt at fusion, providing three or four meeting oms of different sizes, for use by the societies in nmon and in turn, and, in general, making better ovision for the interests common to all without any pairment of their independence in rules, traditions, ocedures or property. When those of us who have en considering present-day needs look at this morandum, presented in 1852, we cannot but mire the foresight and wisdom of our mid-Victorian edecessors.

An opportunity of housing the scientific societies us, as a community of co-operative but substantially ependent units, was actually presented in the same ar, 1852, by the offer of accommodation in new buildings then being planned on the estate at Kensington Gore, acquired with the proceeds of the 1851 Exhibition. We begin to see the benevolent interest of the Prince Consort in our concerns. Kensington Gore, we must remember, in those days of horse transport, was still on the rural margin of the suburbs; and, in gratefully declining the offer, the Royal Society and its associates urged upon the Government the desirability of housing the scientific societies centrally and, if possible, under a single roof. The acquisition by the Government, some years earlier, of Burlington House and its grounds, extending from the Piccadilly frontage through to the street which is now named Burlington Gardens, seemed, indeed, to have provided the ideal opportunity for giving effect to such a plan.

The Prince Consort, with a vision of the future meaning of science far in advance of his time, privately urged the five scientific societies to press their claim to the site. It had been understood, indeed, that the primary intention of the Government in buying Burlington House had been to provide accommodation for the learned societies. Lord Wrottesley, then president of the Royal Society, personally canvassed the Government, making it clear "that the desire of the chartered societies for juxtaposition and for the Burlington House site was unabated". Failing that, he indicated, they would be glad to be lodged in the buildings then occupied by the Royal Academy, that is, in what is now the National Gallery. The danger of a rival claim had become clear, and had, indeed, been mentioned to the Royal Society by the Prince Consort. It appears that the Government had already made some kind of commitment to the Royal Academy, so far as the mansion of Burlington House was concerned. It would take much too long to discuss even what is known of the rival lobbyings of those days. It must suffice for this occasion to recall the results, and to lament the fact that a magnificent opportunity was lost, which would have given London a scientific centre worthy of the nation's achievement. We cannot blame our predecessors, who probably did all that was possible; nor can we grudge their success to our friends of the Royal Academy, who are in no way to blame for taking what was offered to them.

If the Government, indeed, had then used Burlington House and its grounds to discharge only these two of the obligations to which it was to some degree committed, the needs both of the scientific societies and of the Royal Academy could still have been handsomely met, and adequate scope for future development could have been ensured to both. The mansion itself with the wings of the front courtyard, already scheduled for rebuilding, could, for example, have been allotted to one, while the other of the two claimants could have had a new building, with frontage at the north end of the gardens, and ample space for extension southwards over them, to meet increasing needs and new developments. The Government, however, used Burlington House first to satisfy a third obligation which it had accepted, to house the University of London, then only a degree-giving body requiring space chiefly for the periodical examination of large numbers of candidates. In 1858,

---

From the presidential address to the Royal Society delivered on ember 30.

the continued pressure of the scientific societies and the Government's own desire to recover the rooms in Somerset House led to the offer of the use of Burlington House to the Royal Society, subject to the condition that for the time, and pending rebuilding on the sites round this courtyard, the Linnæan and Chemical Societies should be accommodated with us in the mansion, and that the University of London should still be able to use the large rooms in it for examinations. It is curious to reflect that this temporary arrangement gave to the Royal Society and its associates their only opportunity to this day, even to share the use of a room suitable for a meeting of more than very modest dimensions.

In old Burlington House, then, we were established, and were to remain there with the Chemical and Linnæan Societies for some fifteen years; and an appearance of stability had at first been given to our occupancy by the mention of plans to build a new examination hall for the University of London on the western side of this quadrangle, and to allow the Royal Society to use this also for large meetings and for its gallery of portraits. Two later developments, however, dispelled any such hopes. In 1867 evidence came to the Society, first through a statement in *The Times*, that the Government had decided, after all, to give the Royal Academy a permanent lease of Burlington House and the right to extend northwards by building over its gardens. At about the same time, and presumably in fulfilment of another commitment, the large building which now fronts on to Burlington Gardens was begun, to accommodate the University of London and its examinations, and was opened by Queen Victoria in 1870.

The scientific societies were not, indeed, to be homeless; but the only possibility now left was to accommodate them in the buildings planned to be erected round this front courtyard, where they have been ever since. The total space thus offered did, indeed, allow more room to each of the societies than it had previously enjoyed, even after the Society of Antiquaries, at the Royal Society's instance, had been included in the scheme. But the space now available could not easily be planned for the sharing of meeting rooms and general facilities, or for a central federation of the libraries, or for any of the features of the earlier plan which would have enabled the societies to function as independent members of a real scientific community. The scheme had an even more fatal defect. The plans were made on the assumption that the societies existing in the 1860's, with their respective dimensions and requirements at that date, would provide a pattern of the needs of science for all time, or at least for the life of buildings designed to mid-Victorian standards of permanence. Each of these societies, therefore, with the approval of the Royal Society we must admit, presented its separate claim and had it embodied in the solidity of the buildings we still inhabit, filling the available space completely and precluding any later expansion, rearrangement, or new admission to the circle thus finally closed. Societies which have changed but little in numbers or activities may have had little reason, even yet, to complain of the accommodation which they acquired. For others, the allotment which had been regarded then as satisfying future needs for half a century at least became obviously inadequate very much earlier.

In 1900 came news that the large building on the Burlington Gardens frontage was to be vacated by the University of London, and tentative inquiry was immediately made as to the possibility of allotting to the Royal Society, on the ground that "the prese rooms occupied by the Society were rapidly becomi inadequate". The Government, however, had alrea decided to transfer the building to the Civil Servi Commissioners, and it has continued to be dedicat to its original use for large-scale examinations, sa for the later assignment of certain rooms in it to o much younger sister, the British Academy. It w be noted that the Royal Society was finding i quarters here inadequate so early as 1900, twent seven years after it entered them, and before the was even any prospect of the great expansion of i responsibilities and activities in recent years. O accommodation is still the same to-day, after seven years. Our walls cannot find room to hang o important collection of scientific portraits, and o great library is badly overcrowded, even though have parted with some of it to give better housin for a time, to the remainder; and it continues, course, to grow. Library pressure, in fact, is felt varying degrees by all the societies here; and I thi that it is still true, as some of our predecessors s already in the 1850's, that no scheme will be able deal with this problem efficiently, and to meet mode needs without disturbing historic associations, whi does not include some kind of central co-ordinati of libraries. The lack of a lecture or confere room, available in common for larger meetin and well equipped with modern resources for p jection and demonstration, is another acutely f need.

There are greater needs and anomalies, howev than any of these common ones. Of all the societies Burlington House the Chemical Society, which w originally satisfied with the poorest allotment of roo has undergone the greatest expansion. In the 1860' had a membership of some 450; it now has ab 5,000. Its library, of great importance to all work in chemistry, whether fundamental or applied, has burst the bounds of its accommodation, that a p of it is deposited in the crypt of a neighbour church; and the Chemical Society's meeting roo in every way unsuitable, and inadequate to meanest conception of the regular needs of a soci of its standing and numbers. Apparently our p decessors of the 1870's did not see much future chemistry. On the same evidence, they did foresee any future for physics at all. The Physi Society did not then exist; by the time it was bo there was no room for its admission, and the St has never offered it a home. The same is true other societies formed later to deal with functio aspects of biology and other new fields of knowled For most of their meetings these newer societies and need the facilities available in academic a research institutions. A national centre of scie however, should be capable of progressive adjustm to changing needs, and we ought to be able to m new admissions, on a varying scale of allotment, the central community of societies.

What then should we be doing to deal with situation? Actions and decisions long past h imposed it upon us, and regrets and repinings o an opportunity lost more than seventy years ago not help us to-day. We must admit, too, that present quarters, with all their defects of elastic have provided a combination of central position w freedom from noise of traffic which might be har find again. Let me say, then, that the Royal Societ officers, having consulted with the officers of ot societies here, and particularly of those whose needs are urgent or whose interests might be directly concerned, have not yet abandoned the attempt to find a solution which would not involve the removal of any from the Burlington House estate. If we fail in that direction—and there is no ground for optimism—the problem will remain, and the time is not one for neglect or postponement of action.

On all hands we hear talk of reconstruction and see plans for the rebuilding of London. We cannot expect another Christopher Wren—one of our original fellows and a leader in the science of his day; London missed that opportunity. It is natural and proper for the plans now being presented to make spacious and impressive provision in the new London for opera, drama, music and all the fine arts; and we shall surely join in a general welcome to any practicable scheme which can open the doors more widely to such cultural privileges, and enhance their dignity and worth in the eyes of London and of the nation. But I do not think that we must stand by and allow the claims of science again to go by default. A fear of over-statement, a passion for critical accuracy which is a part of the very spirit of science, may make us reluctant advocates. If necessary, however, we must be ready to remind all who may be concerned of the part which the British scientific effort has played, in making it possible now to plan at all, with confidence, for our own civic and national reconstruction. But for science, we may remind them, the very different plans which our enemies were so recently making for our future might already be taking effect. I have no doubt that the claim will be handsomely admitted; but we ought not to be too easily appeased with compliments and oratorical bouquets. The nation's opportunity, when peace returns, of enjoying the arts and the amenities of life will be dependent on its standards of health and prosperity, and these, in turn, ever more directly on science and its applications, as certainly as these are still needed to secure our national survival and victory in this War.

This ancient Royal Society of London, and those societies which have grown from it and around it in later years, constitute a scientific organism which is a national and imperial heritage, second to none in the world's esteem. Here are the roots of the spreading tree of science and technology, which should form a major component of our national contribution to the new world now in the making. Seventy years ago these roots were given only enough soil for the replanting then undertaken; they have long been badly pot-bound, and some parts of the root system are threatened with strangulation, while others have appeared outside the pot. We can properly claim, I think, that the progressive needs of our scientific societies shall be given early consideration, in any new allotment which plans for reconstruction may allow. We ought to have a scientific centre permitting them to co-ordinate their activities with economy, and giving room for change, expansion and organic growth by budding and division, in accordance with Nature's law. I think that we have the further right to expect that the home of science, in this capital city, will have a dignity symbolizing its value to the nation and the empire, and enabling us to hold up our heads in the company of other countries, whose scientific academies, not more famous than ours, have so long been housed more worthily, and with a more generous recognition of their due place in an enlightened people's scale of cultural values.

THE COMING OF PLYWOOD

A REVOLUTION IN THE UTILIZATION OF TIMBER

THE return to wood in the construction of certain types of aeroplane has given rise to some new factors in the future utilization, or perhaps more correctly expressed, in modifications in the utilization of the remaining timber supplies of the world. Generally speaking, the most important property in materials used in the construction of aeroplane structures is great strength combined with lightness. As a result of research in India (vid. *Ind. For. Records.* "Indian Timbers for Aircraft and Gliders". Delhi: Manager of Pub., 1942) the strength to weight ratios for several materials are as follows: material, Sitka spruce, M. of R./sp. gr., 25,500; Douglas fir, 24,000: Indian spruce, 26,000; Indian fir, 25,900; ash, 25,800; teak, 24,800; *Michelia excelsa*, 25,100; *Polyalthia fragrans*, 21,300; *Phoebe goalparensis*, 22,600; *Canarium euphyllum*, 22,400; duralumin, 21,300; carbon steel, ordinary, 12,700; nickel-chrome steel tempered, 23,600.

These figures at once give the reason for the pre-eminence of spruce in aircraft construction in Europe and America. Weight for weight, it is stronger than the best alloy steel and much superior to duralumin, of which a great many metal aircraft are constructed. Owing to its low specific gravity, timber is also suitable for long members subject to buckling or combined binding and compression. In such cases it is said to be generally easier to increase considerably the moment of inertia of a timber section by simple processes than is possible with metal members without increasing the weight. It may be briefly mentioned that timber is used in aircraft construction in the wings, body-work, tail, airscrews, and the covering of the framework. For the main members, such as the spars which support the wings, the longerons which support the body framework, and the tail members, only faultless timber of the highest quality is accepted. For these parts and other members of the framework, selected Sitka spruce is usually used. Wooden airscrews are mostly of walnut and mahogany. In the covering of the wing surfaces and body frames plywood is used, selected birch being one of the best woods. The construction of gliders is similar to that of aeroplanes, and requires the same consideration of strength and weight. It thus becomes evident that very strict specifications must evidently be in force, and only timber of the highest quality will be accepted for aircraft construction. But a high proportion of this material is required in short lengths only.

In connexion with plywood generally, a "Note on the Manufacture of Plywood in India" (*Ind. For. Rec.*, Utilis., Res. Inst. Delhi: Manager of Pub., 1942) gives information on the prospects of the industry, on existing plywood mills in the country, on possible areas for exploitation, on glues and the manufacture of plywood and tea boxes. It also discusses the machinery required for a plywood mill and the manufacturing costs. A list of timbers considered suitable for plywood work in India is also given. Plywood research is not new to the Research Institute at Dehra Dun. For many years since its inauguration this research was carried out by Mr. W. Nagle, the officer in charge of the Wood-working Section. He retired in 1940, the memorandum in question being written by S. W. Kapur, who has had the additional advantage of having studied Japanese methods of plywood manufacture.

The question of veneers, the foundation of plywood, is dealt with in another publication (*Ind. For. Leaflet* No. 34. Dehra Dun, U.P.: For. Res. Inst., 1943) entitled "Types of Seasoning Kilns suitable for Drying Indian Woods", already referred to in NATURE. On these questions of seasoning veneers the following is of importance: "Thorough seasoning of veneers before gluing and manufacture into plywood is very important, if satisfactory plywood is to be made. Green veneers can be air-seasoned or kiln-dried exactly like ordinary wood. The usual method in Europe and America, for the quick seasoning of veneers, is to dry them in long progressive dryers. These dryers are closed metal chambers 50 ft. to 100 ft. long, fitted with powerful fans for the rapid circulation of air, and with steam-heated pipes for raising the temperature of the air circulating inside the dryer. The green veneers are fed into one end of the drying chamber and slowly moved towards the other end by means of endless belts or between rollers fixed along the length of the dryer. The speed at which the veneers move can be controlled, but they are usually dried in the course of a few minutes which they take to travel from one end of the dryer to the other. Unfortunately progressive dryers are very costly."

It is pointed out, however, that the above type of dryer is not essential for the quick seasoning of veneers, and it is possible to use certain other types of cheaper kilns.

Under the title "The Forest Giant goes to War" (*Christian Science Monitor*, January 9, 1943) details are given of the heavy fellings being made in forests in the United States. The following extract portrays an increasingly serious position. "Even within the Douglas fir region itself, where the facts are at hand, there are forebodings that the tide of war demands for 'the most critical species of lumber in the United States' will leave a wake of wholesale destruction in this incomparable resource. The production of what the trade terms 'West Coast lumber' from the region of 1941 was 8,500,000,000 feet. This was principally Douglas fir, but also included its companion species —West Coast hemlock, Sitka spruce, and Western red cedar. In 1942, production was running about 3 per cent ahead of 1941, despite severe shortages in manpower and equipment. The annual war-time cut is thus roughly 1½ per cent of the region's stand of all species of sawtimber. One fact of importance on this figure is that the choicest grades of timber, such as airplane spruce and 'peeler' Douglas fir, are being overcut. Certain areas also are being overcut, particularly the forests that remain close to tide-water and to rail outlets."

Plywood has now become one of the chief factors in timber utilization. This new factor may be well termed revolutionary in its future possibilities, coupled with the modern plywood mill or factory. In professional circles the latter was regarded as more or less of a Cinderella before the outbreak of war, and only the few visualized it as one of the chief methods of utilizing timber in the future. War developments would seem to have proved this without any reasonable doubts. How will this benefit mankind? It is not difficult to frame an estimate. The exploitation of the primeval forests of the globe, both conifers and broad-leaved, have in the past left much to be desired, the waste in conversion, both in the forest and the sawmill, having been excessive. The forest war fellings are accentuating this deplorable wastage. In the past, in the tropical forests consisting of a large number of species growing in mixture of which so far but a few have had any marketable value, and only one or two of these a world value, the waste in extraction of these latter, owing to the excessively high specifications laid down by the buyer, has been enormous. Great logs with slight external flaws in them and giant butts which would not fulfil the buyer's terms were left to rot in the forest—material of a priceless value. Outside the forest has lain in wait the sawmill. These latter have been vastly improved during the past half-century—but it has not proved possible to eliminate a considerable waste in conversion, especially in sawdust. It is being demonstrated that the modern plywood mill has reduced the waste of timber, the raw product, to a very low percentage. So far as the remaining hardwood forests of the world are concerned, tropical and otherwise, plywood utilization would seem to indicate that their economic life (that is, utilization) can be prolonged, if not indefinitely, at least for a far longer period. For one thing, by means of plywood a larger number of previously unutilizable species in the great rain and deciduous tropical forests will become commercially practicable; while the appalling waste in the conversion of the so-called luxury timbers, current up to date, can in future be eliminated to a considerable extent by the erection of a modern plywood mill in the vicinity of the forest under exploitation.

The modern plywood mill, more correctly designated perhaps as a factory in its most up-to-date war-built design, may be regarded as considerably ahead of its predecessors, and has been the outcome of much thought and careful planning on the part of men who had made a thorough study of the problems to be met. Its erection involves a considerable initial outlay, which during war-time, it is said, has been fully justified due to two facts: the finished product is of the highest order and it is produced very expeditiously.

It is not the object of this article to describe the mill and the various stages through which the material produced by the rotatory cutter or peeler machine finally emerges in its plywood form. It is the possible enormous increase in out-turn per unit of forest to which attention is here directed. The logs—the larger the diameter the better within limits—arriving at the mill are cross-cut to the size required, not less than 7 ft., for the rotatory cutter, which is really a large-scale lathe. The barked log is placed between two spindles which are clamped into the centre of the ends and rotated against a fixed knife which runs the whole length of the log and thus takes a thin shaving off the whole circumference. The knife moves forward at a set speed, which is dependent upon the thickness of the shaving. It will be understood that until the log has been turned to a perfect cylinder only scrap material comes off, though even this is utilized. Once a perfect cylinder is achieved, the veneer comes off as a continuous (moist) sheet which is wound on to a drum. Veneers as thin as 1/90 in. can be cut in the most modern machines. The logs are turned down to an 8–9 in.-diameter core. The core may have defects, but in any event below this the small radius of curvature renders it brittle, the veneer thus splitting. The cores are now made use of for other purposes. In fact, in the modern mill, waste has been almost entirely got rid of. The roll of veneer after leaving the rotatory cutter passes through a number of processes before actually arriving at those in which its manufacture into the particular type of plywood being turned out is undertaken. Most of these processes are in the hands of women and are by no means uninteresting, while the condition in which the women work with artificial sunlight and the latest aerating devices are excellent.

The modern plywood factory is nothing short of a revolution in the prolongation of the life of, notably, the remaining primeval forests on the globe. Each log from each big-sized tree felled in these forests in the future can be put to its full use by man with the minimum of waste. The annual requirements in logs from any forest will thus be restricted automatically, and the existing amounts of timber still available be spread over a longer period.

Never perhaps in the history of the world has such a prolongation been more necessary, for never has a timber famine in one form or another loomed larger on the horizon. But man's cleverness in producing and perfecting the plywood mill will prove of little use unless the Governments of the chief countries concerned come together, and see that its apparent special advantages are made use of, and are not suppressed by existing vested interests, which have little in relation with the true economic uses and exploitation of the forest.

THE U.S.S.R. ACADEMY OF SCIENCES

JUBILEE SESSION

THE Soviet Academy of Sciences celebrated the twenty-fifth anniversary of the U.S.S.R. by a special jubilee session held at Moscow on November 15–18, 1942, and the papers read at the session have now been published in a very neat volume of 250 pages. Apart from the texts of the greetings messages sent by the Academy to Soviet leaders, to fighters of the Red Army and the Navy, to men of science of the world, etc., the volume contains a series of surveys of the progress achieved in the various spheres of the Academy's activities during the twenty-five year period.

Prof. A. A. Baikov reviewed general development of the Academy which in 1917 consisted of three sections (physico-mathematical; Russian language and literature; and historico-philological), with forty-five academicians and 212 other scientific and technical staff. By 1941 the Academy had eight sections (physico-mathematical; chemical; geologo-geographical; biological; technological; historico-philosophical; of economics and law; of literature and languages), with seventy-six institutes, eleven laboratories, forty-two stations, six observatories, twenty-four museums, in which were working 118 academicians, five honorary academicians, 182 corresponding members and 4,700 scientific and technical personnel.

Apart from these quantitative changes, the scope and the character of the work have also undergone great evolution, mainly in the direction of a closer contact between pure research and its applications. This tendency has found its practical expression in the elections to the Academy of a number of eminent engineers, industrial chemists, etc., and culminated in the organization in 1935 of a section of technology. In 1934 the Academy was transferred from Leningrad to Moscow and taken under the immediate control of the Soviet of People's Commissars which discusses and approves plans of research. In 1938 the Soviet recommended the Academy to concentrate its attention on the leading scientific problems necessary for the development of socialistic economics and culture. In 1939 the Academy elected J. V. Stalin as its member, and this event was regarded as a symbol of transformation of the Academy into the "general staff of Soviet science". Since the outbreak of war, the Academy has concentrated its attention on problems connected with the mobilization of natural resources for military purposes. Among such problems an outstanding place belongs to the work of a special commission for the mobilization of resources of the Ural, where great progress has been achieved in the scientific organization of metallurgical industry, and of Kazakhstan, where great reserves of coal, copper, nickel, etc., were discovered.

Prof. A. F. Joffe produced a summary of the development of exact sciences in the U.S.S.R. during the past twenty-five years. In 1918 the Institute of Physics and of Bio-physics (P. P. Lazarev), Physico-technical, Roentgen (A. F. Joffe) and Optical (D. S. Rozhdestvensky) Institutes were founded in Moscow. The Physico-Technical Institute supplied personnel for similar Institutes at Tomsk, Kharkov, Dnepropetrovsk and Sverdlovsk. The Physical Institute of the Academy (L. I. Mandelstam), which moved from Leningrad to Moscow, became a leading institution. New problems of application of physics in agriculture are studied by the Leningrad Institute of Agrophysics. Chemical science also has now a series of institutes: of general and inorganic chemistry (N. S. Kurnakov and L. A. Chugaev); of organic chemistry (A. E. Favorsky, N. D. Zelinsky); other institutes are devoted to colloids, electrochemistry, radiological chemistry, applied chemistry, chemistry of fertilizers, pharmaceutical chemistry, etc.

Astronomy advanced at a less rapid rate, but the Mathematical Institute of the Academy has developed into one of the world centres of mathematical science.

The progress of mining technology and of metallurgy, as reviewed by Prof. I. P. Bardin, reveals gigantic work of reconstruction in which academic institutions and scientific workers have taken an honourable part. An even more impressive picture is presented by Prof. A. V. Vinter in a survey of the energetics of the U.S.S.R.—a fascinating story of the utilization of the resources of the water and air, of the great hydro-electric installations, of the electrification of transport, etc.

In the biological sciences, as reviewed by Prof. L. A. Orbeli, the progress was mainly in the direction of planned research, concentrated on the leading problems of the Darwinian theory of evolution, which are studied not only in laboratories but also in the field. Spectacular progress can be registered, of course, in physiology as a heritage of the late Prof. I. P. Pavlov. Investigations of the floristic and faunistic natural resources of the Soviet Union are proceeding apace and many volumes of the "Fauna of U.S.S.R." and the "Flora of U.S.S.R." have been published.

The geological sciences (V. V. Obruchev) have made one of the greatest contributions to the economic development of the Union, and the Academy took an active part in the extensive and exhaustive investigations carried out by hundreds of expeditions in the remotest corners of the Union.

Not less than seven papers, occupying well over half of the volume, are devoted to the humanitarian sciences: the importance and place of the great October revolution in the history of mankind (E. M. Yaroslavsky); twenty-five years of the great October revolution and the patriotic war of the Soviet people (G. F. Alexandrov); Soviet State—a State of a new type (A. J. Vyshinsky); philosophical science in the U.S.S.R. during twenty-five years (M. B. Mitin); development of historical sciences in the U.S.S.R. during twenty-five years (B. D. Grekov); Soviet historiography (E. V. Tarle); a quarter century of Soviet literature (A. N. Tolstoi).

OBITUARIES

Sir William Noble

SIR WILLIAM NOBLE, who died on November 10 at the age of eighty-two, had devoted the whole of his active and strenuous life to the service of electrical communication, in which he rose from the humble grade of telegraph messenger to the leading position in the British Empire. He was appointed as a Post Office telegraphist at Aberdeen in 1877 at the age of sixteen, and at once began to show a keen interest in the electrical and technical sides of the telegraph service. He gained many medals, prizes and other honours and after a few years became a lecturer in electricity and telegraphy at Gordon's College, Aberdeen. It was not, however, until 1893 that he obtained a transfer to the P.O. Engineering Department as sectional engineer at Aberdeen. He soon attracted the notice of his departmental chiefs and thereafter his advancement was rapid. In 1897 he was personally selected for appointment as first-class engineer on the headquarters staff in London, by Sir John Gavey, who had had occasion to observe a highly original and efficient means he had devised for the mechanical testing of telegraph poles. Further promotions carried him through the grades of technical officer, assistant superintending engineer, and staff engineer, to that of superintending engineer for the London District in 1907. In 1912 he became assistant engineer-in-chief and in 1919 he succeeded Sir William Slingo as engineer-in-chief, a position which he held until his retirement from the Government service in June 1922.

Sir William Noble, who received a knighthood in 1920, was intimately concerned with all the many scientific, technical and commercial developments of the Post Office communications services during his long period of responsible office. As an administrator he had a genius for selecting the right man for the right place; he made quite exceptional efforts to make and maintain personal acquaintance with all the leading personalities of his great staff throughout the country. Every good and enterprising officer could count upon his understanding assistance and support, and he was accepted as guide, philosopher and friend by all.

Shortly after his transfer to headquarters in 1897 he plunged into the heavy work of the initial 'telephoning' of London on the basis of underground multiple cables in all central areas and the 'central battery exchange' system throughout. This involved pioneer work of much diversity and the careful gathering and maturing of experience in readiness for the complete transfer of the National Telephone Company's local exchange system to the Post Office in 1911. (The National Trunk Line system had been transferred to the Post Office in 1895.) The full transfer in 1911, and its aftermath, also brought him much strenuous work, not the least of which was the unification and fitting in of the large technical staff of the National Telephone Company with that of the Post Office; in this delicate work he played by far the most important part, and its smooth and successful accomplishment stands to his credit. He had the subsequent development of the new situation well in hand when unfortunately the outbreak of the War of 1914–18 put a stop to everything. The changed financial situation and the industrial difficulties and confusion of the early post-war years introduced further obstacles, and meanwhile public criticism of the shortcomings of the country's telephone service became acute. Sir William's manful efforts to put the past and the future in proper perspective, both in the public Press and before parliamentary committees, will still be within the recollection of many.

When, a little later, Parliament set up the Geddes Committee with instructions to wield the economy 'axe' among Government departments, Sir William's able demonstration of the economic side of the Post Office Engineering Department, and its methods of continuously assessing and fostering the efficiency of capital and maintenance expenditure in all districts, carried conviction, with the result that his Department was one of the very few Government departments to receive a complimentary testimonial from the Geddes Committee.

Sir William was deeply interested in, and did much to encourage, the adoption of long-distance trunk telephone cables in place of overhead wires on pole lines. Even before the advent of the telephone repeater, communication from London to Birmingham, Leeds, Manchester and Liverpool had been provided by means of multiple twin cables carrying comparatively heavy copper conductors. On the invention of the thermionic valve, with its almost limitless applications to the amplification of high-frequency electrical oscillations, he recognized at once that the situation had been transformed by the introduction of a new factor which would place the means of achieving world-wide telephony in the hands of his successors.

His interest in radio communication was continuous from the early days in which he assisted Sir William Preece in experiments in inductive (or perhaps one should say earth conductive!) wireless telegraphy between parallel wires along the opposite sides of Loch Ness, up to the times when he was chairman of the first Broadcasting Committee and afterwards one of the founders of the British Broadcasting Company, of which he was a director from 1922 until 1926.

The development of the automatic switching systems of telephony was another subject very near his heart, and one in which he retained an active interest after his retirement from the Post Office in 1922 when he became a director of the General Electric Company. From that date until quite a short time before his death he was managing director of that Company's telephone manufacturing works at Coventry, a source from which has emanated much of the automatic switching plant, telephone repeater equipment and many other items of communications engineering used by the Post Office and other administrations.

Sir William's commercial and social activities were many and varied. He made many friends and few if any, enemies. On his professional side he may be summed up as a man of abounding energy, vision and executive power.

Sir William was always proud of his Aberdeen origin and the feeling was mutual; "a citizen of no *mean* City", he used to say. T. F. PURVES.

Dr. Alexander Lauder

ALEXANDER LAUDER died at Greenock, his birthplace, on November 11, at the age of seventy-three. He studied first under Prof. Dittmar, in what is now the Royal Glasgow Technical College, and then with Prof. Crum Brown at Edinburgh before taking up his first appointment as assistant to Prof. (later Sir J. J.) Dobbie in the newly founded University College of North Wales at Bangor.

In addition to assisting in the Chemistry Department, he took up the study of agricultural chemistry and carried out experimental work, more particularly n connexion with the field experiments. In conunction with Prof. Dobbie, he made an elaborate nvestigation into the alkaloids of *Corydalis cava* and worked out the constitution of these alkaloids, the results being published in a series of papers in the *Journal of the Chemical Society* (1892–1904). Along with Prof. Dobbie, he took up the study of absorption spectra and investigated the connexion between the chemical constitution and the absorption spectra of certain organic compounds, in which work they were pioneers.

In 1904 Dr. Lauder was appointed head of the Chemistry Department of the newly founded Agricultural College, Edinburgh, and in 1907 also became esponsible for the teaching of agricultural and forest chemistry to the University degree classes. In addition to his teaching, he carried out many investigations in various branches, giving particular ttention to the composition of milk as affected by the feeding of the animal, the composition of swede turnips and heather and differences of a chemical nature in potato varieties. Most of that work was published in the *Scottish Journal of Agriculture* and in *Agricultural Progress* or in special reports. He retired in 1936.

Dr. Lauder had also a long record in administration, for he acted at various times as secretary and treasurer to the College and as director of studies for four or five years immediately after the War of 1914–18. He served on the councils of the Royal Institute of Chemistry and the Society of Chemical Industry, and was chairman of the East of Scotland Branches of the Chemical Society and the Royal Institute of Chemistry. He was prominently identified with the work of the Royal Society of Edinburgh and served on the council for ten years and was assistant secretary to the ordinary meetings for five years. He also took an active share in the work of the British Association, being for a time secretary of the Agricultural Section, and president of the Section for the Leicester meeting in 1933 when the subject of his address was "Chemistry and Agriculture".

Dr. Lauder was much interested in music and in English literature. He was a member of the Reid Orchestral Committee for many years, an active member of the Bach Society, and various other musical bodies. He had accumulated a library of standard English works, the study of which gave him much pleasure.

By those who knew him, he will always be remembered for the services he gave so ungrudgingly, for his sound judgment, for his wit and generous nature.

WE regret to announce the following deaths:

Prof. J. Macfarlane, emeritus professor of botany in the University of Pennsylvania, on September 16, aged eighty-seven.

Prof. Umetaro Suzuki, president of the Scientific Research Institute, Manchukuo, emeritus professor in the Imperial University of Tokyo, aged sixty-nine.

NEWS and VIEWS

Presidential Address to the Royal Society

IN the course of the presidential address to the Royal Society, delivered as customary on St. Andrew's Day, Sir Henry Dale noted that Sir Henry Tizard, foreign secretary of the Society, has returned from a scientific mission to Australia, and that Prof. A. V. Hill, the senior secretary of the Society, has gone to India as a result of a request sent to the Society by the Government of India. Prof. Hill is to consult with that Government on scientific affairs, and in particular is to advise on scientific and industrial research in relation to measures of post-war reconstruction, and on the co-ordination of such plans in India with corresponding activities elsewhere. During his absence, Prof. E. J. Salisbury will take Prof. Hill's place as biological secretary of the Society. During his visit to India, Prof. Hill hopes to carry out a unique ceremony. It is part of the formal admission of fellows of the Society that they subscribe the obligation in the Charter Book; of the six Indian fellows, only two have hitherto been able to do this. Prof. Hill has accordingly been provided with a sheet of suitable parchment on which the fellows' obligation is inscribed, and the four Indian fellows who have not yet signed the Charter Book will be formally admitted to the Society.

Sir Henry Dale then passed on to discuss the needs of research. He claimed for science its share of credit for the change of prospects now apparent in the War; and remarked that while science cannot afford to relax its efforts, it must also look to the future. If Great Britain is to hold its place alongside new civilizations built from their foundations on modern science, such as those of the U.S.S.R. and China, we must think of research on a higher as well as larger order than hitherto. The Royal Society will welcome any movement advocating great expansion of the nation's support of applied research, whether through the Government's Research Councils, through Departments concerned with the uses of science for defensive preparations in peace-time or for other national interests, or with the training of recruits for research by the universities. Fundamental researches also must not be neglected. British discoverers are as great as any in a world era of great discovery, but often they have lacked proper equipment and accommodation. They must not be so handicapped in the more pressing times to come. The Council of the Royal Society has appointed a committee to consider the needs for fundamental researches in physics; no doubt other departments of science will have similar needs. The primary duty of the Royal Society is to aid researches which seek the advancement of knowledge without immediate reference to its use, though it appreciates clearly that such progress is often necessary to practical advances. Finally, Sir Henry referred to the need of the Royal Society for a home more worthy of its importance; he spoke of investigations which have been made, with the help of the assistant secretary, Mr. Griffith Davies, of the different homes the Society has occupied. Elsewhere in this issue (p. 649) we print Sir Henry's remarks on this topic.

Scientific Work in India

In the August number of *Discovery*, Sir Lewis Fermor gives an interesting account of the history and development of pure and applied science in India. It is well known that India possesses a very ancient culture and civilization. As regards ancient science, the Hindus made important contributions to mathematics, and, as Sir Lewis points out, they possessed a considerable knowledge of zoology, medicine and chemistry. Sir Prafulla Chandra Ray's book on the "History of Hindu Chemistry" from the earliest times up to the middle of the sixteenth century A.D. provides valuable information concerning this branch of science. The conquests of Alexander the Great gave India an important stimulus to intercourse with Europe, but, as Sir Lewis observes, much ancient Indian science antedates this Greek influence. Moreover, it must not be forgotten that when the Arabs brought science to Europe, their knowledge derived from Indian as well as Greek sources. Although in its earlier days the East India Company did not employ scientific men as such in India, it is a striking fact that James Prinsep, one of the Company's official assayers, deciphered in 1838 the ancient Brahmi script used in the rock-cut inscriptions or edicts of the Indian Buddhist king, Asoka (died *circa* 237 B.C.).

According to Sir Lewis Fermor, the modern development and study of science in India began with the coming in 1783 of the Puisne Judge of the Supreme Court, Sir William Jones, who in 1784 founded the "Asiatick Society", later to become the Royal Asiatic Society of Bengal. A portrait of Sir William Jones accompanies the article. Concerning the very great development of Government services depending on applied science, universities and colleges, scientific societies, scientific journals, and academies of science, which has taken place in India during the nineteenth and especially the twentieth century, readers will find here an excellent account. The universities, colleges, and academies of modern India, including the Indian Institute of Science at Bangalore, founded by the eminent Parsee family of Tata, make important contributions to the advance of pure and applied science. A number of these discoveries are referred to by Sir Lewis, who adorns his article with the photographs of eight eminent Indian men of science, namely, Dr. H. J. Bhabha, Sir Shanti Swarupa Bhatnagar, Dr. K. S. Krishnan, Sir C. Venkata Raman, Prof. M. N. Saha, Prof. B. Sahni, the late Sir J. Chandra Bose (all fellows of the Royal Society), and Sir P. Chandra Ray.

Insulin Colour Code

Noteworthy steps in the direction of co-operation in production and distribution have been made by the four firms (Allen and Hanburys Ltd., Boots Pure Drug Co. Ltd., British Drug Houses Ltd., and Burroughs Wellcome and Co.) entrusted with the manufacture of insulin in Great Britain. These firms mindful of their special responsibilities to the diabetic community, have throughout the War period pooled their research, manufacturing and distributive facilities to ensure an adequate and uninterrupted supply of their products to those in daily need of them and to reduce their prices, in the face of rising material and labour costs, to the lowest practicable level Three distinct types of insulin—Unmodified Insulin Protamine Zinc Insulin and Globin Insulin (with Zinc)—are in regular use in Great Britain. Alternative strengths of two of these make a total of six different preparations, and confusion between them might easily be attended by serious consequences To reduce this possibility to a minimum, the British insulin manufacturers have agreed to adopt a uniform design for labels and cartons, by which each type and strength of insulin, of whatever make, wil be readily identifiable by a distinctive colour scheme In addition, the unit strength per c.c. will be displayed in bold figures on both label and carton. An explanatory card, printed in colours, is obtainable from any of the manufacturers on request. The change which will take place on January 1, was made afte consultation with leading authorities and with the approval of the Ministry of Health.

Animal Population of a Seaport

An exhibit entitled "The Population of a Seaport was recently installed in the Zoology Department o the National Museum of Wales. It is based on the fac that any great city to-day is a habitat characterize by a particular community of animal species; i this case including, and largely dependent on, man Examples of this urban fauna—certain birds, domestic animals, rodent and insect pests, etc.—are shown and the interrelationships of the species, betwee themselves and with man, illustrated by coloure tapes running from one animal to another and thenc to a small bust representing man. As man create the habitat for this community, he can control i for the better, notably by improved town-planning whereby, for example, desirable bird-life may be increased, and improved house-building, whereby rats cockroaches, etc., may be diminished. As indicate in the labels, these and some other urban pests wer originally introduced by shipping, and specimens ar displayed of the numerous alien species that thu reach our seaports; those which have establishe themselves, however, have mostly spread inland and are to-day familiar in all large towns. As abou 80 per cent of the population of Britain are urba dwellers, such an exhibit should assist the majorit of visitors to envisage this biological background t their environment, and the advantages to be achieve by its improvement and control. An article describing the exhibit appears in the October number of th *Journal of the Royal Institute of British Architects.*

Recording Cathode Ray Oscillograph Traces

The technique of recording cathode ray oscillograph traces was the subject chosen for the Novembe meeting of the Association for Scientific Photography the speakers being Mr. W. Nethercot (E.R.A.) and

Mr. N. Hendry (Rotax, Ltd.). Mr. Nethercot's paper dealt with the recording of high-speed transient phenomena by hot-cathode glass-bulb tubes, and examples were shown of wave-forms of 20 Mc./sec. and above. In single transient recording the beam raverses the screen only once, and the exposure ime of the film is therefore determined by the duration of the glow from the screen, since the actual traverse time may be only a fraction of a microsecond. Photography by direct contact of he film with the screen has so many disadvantages that it is only suitable for transients of simple wave-shape where blurring of the trace and curvature of the screen do not affect the result appreciably. The most satisfactory method is by means f a specially designed camera.

Since the majority of the light emitted from a blue-screen tube (the optimum material for recording) is in the blue-violet region, it is not necessary to use an achromatic lens; further, the corrections necessary or a high-grade camera lens are not required for scillographic recording at a fixed distance. The best results are obtained with ortho emulsions; with panchromatic films the glow of the tube cathode frequently caused fogging on the centre of the record. Mr. N. Hendry, in dealing with the requirements of both cameras and tubes for recording, pointed out that small changes in the setting of the brilliancy control make large differences in the apparent recording sensitivity due to change in spectral emissivity of the screen with beam current. For many purposes, particularly where the reproduction of records is not required and the highest speed is not necessary, recording paper is as satisfactory as film, and more economical. The usual mercuric iodide intensifier gives good results, as does also a silver intensifier. In the discussion which followed, Dr. H. Moss (A. C. Cossor) spoke of the correction necessary for screen curvature of the tube, and Mr. G. Parr (*Electronic Engineering*) showed four simultaneous traces on recording paper taken from two gas-focused tubes with electronic switching of the beam.

The Clinical Society of London, 1868–1907

In his recent presidential address on this subject before the Clinical Section of the Royal Society of Medicine, Dr. J. D. Rolleston said that the formation in 1868 of the Clinical Society of London, the parent of the Clinical Section of the Royal Society of Medicine, was mainly due to Dr. Headlam Greenhow and Dr. (afterwards Sir John) Burdon Sanderson, who were both assistant physicians of Middlesex Hospital, the latter being afterwards appointed Waynflete professor of physiology and eventually regius professor of medicine at Oxford. According to Dr. Rolleston, the most interesting historical event connected with the linical Society was the first medical description in reat Britain of X-rays, which was made before it nearly fifty years ago. Early in 1896, the Society invited Prof. Silvanus Thompson to tell its members about the new discovery; a special meeting was held on March 30, 1896, and was attended by nearly four hundred members. Later, numerous cases illustrating the diagnostic and therapeutic value of X-rays were reported at meetings of the Society and recorded in its *Transactions*. A remarkable custom in the practice of the Society was the frequent establishment of special committees to discuss various bjects or individual cases. The most important of these committees were those on myxœdema, the periods of incubation and contagiousness of certain infectious diseases and the antitoxin of diphtheria. The course of the Society was successful from the first. At the time of its amalgamation in 1907 with sixteen other societies it numbered 572 ordinary members and 17 honorary members. The first meeting was held on January 10, 1868, under the presidency of Sir Thomas Wilson, who was regarded at the time as the greatest English physician of the century and was author of a text-book on medicine which was without a rival for more than thirty years.

Early Science in the United States

Two recent issues of the *Proceedings of the American Philosophical Society* (No. 1, vol. 86, 1942, and No. 3, vol. 87, 1943) contain some interesting historical material and illustrations. The first, bearing the title "The Early History of Science and Learning in America with Especial Reference to the Work of the American Philosophical Society during the Eighteenth and Nineteenth Centuries", contains papers read before the Society at its mid-winter meeting in February 1942, and is inspired by the fact that that year saw the close of two hundred years of activity by the Society, which was organized by Franklin in 1743. It certainly seems a good plan to prepare for such a celebration as a bicentenary by the preliminary presentation of papers of this kind, in which various contributors deal with the Society's early activities in a wide range of fields, including, among others, agriculture, meteorology, climatology, engineering, vertebrate palæontology, and so on; there is also an interesting biographical study of James Logan (1674–1751) and a carefully documented account of a memoir by Rafinesque that has been generally overlooked.

The other issue, entitled "Thomas Jefferson", contains papers read before the Society in celebration of the bicentenary of its third president, that great American, Thomas Jefferson, in April of 1943, at the actual bicentenary of the foundation of the Society, which was also the bicentenary of Jefferson's birth. Various contributors ably discuss Jefferson's life and times, his political philosophy, and his many scientific interests and pursuits. Dr. Harlow Shapley's paper on Jefferson as a natural philosopher was printed in Nature of August 14, p. 178. The figures of Franklin, Jefferson and Rittenhouse stand out once more in these pages, and fitly in these days we are reminded of Jefferson's oath of "eternal hostility against every form of tyranny over the mind of man". It is perhaps strange that in two places there recurs the old claim that Hadley's quadrant, "with the aid of which the European nations traverse the globe", was invented by the American, Godfrey, although this matter has been cleared up long ago.

The High-Frequency Marine Radio Unit

An original conception of the Federal Telephone and Radio Corporation, now being adopted by ship architects in the United States, is the marine high-frequency unit—an entirely self-contained, complete, high-frequency ship installation, including transmitter, receiver and power equipment in a single housing with projecting shelf for operating purposes. In addition to providing a simple, flexible and effective way of supplying long-distance communication facilities over a continuously variable frequency range of 2–24 m.c. to any ship, it possesses advantages as regards installation, training, operating and servicing comparable with the marine radio unit. The development of these two units enables ship designers and marine architects to determine well in advance the exact space requirements needed for a complete modern radio room installation for both medium and high frequency. Waste of valuable capacity in the ships' structures can thus be avoided, and, in fact, the new units are already influencing the design of ships' radio rooms. An article by E. J. Girard (*Elec. Comm.*, 21, No. 2; 1943) describes the new high-frequency unit, its circuit features, power supplies and installation. The new equipment employs the unit construction principle for shipboard radio installations. High-frequency radio transmitting and receiving equipment supplements standard frequency installations to provide, through choice of proper frequencies, means of direct communication with points far beyond the range of standard-frequency working. Since long-distance communication on high frequencies is accomplished with relatively low power, economy of operation is maintained even though the range is vastly extended. With elimination of ship-to-ship relaying of messages, accuracy and reliability are improved and communication with home ports is accelerated.

Eclipse of the Sun, Sept. 21, 1941, in the U.S.S.R.

A SPECIAL publication of the Academy of Sciences of the U.S.S.R., which has somewhat belatedly reached Great Britain, deals with the eclipse of September 21, 1941, and contains four papers written before the eclipse. The first, by A. Michailov, gives a detailed calculation of the circumstances of the eclipse in southern Siberia, and includes two charts from which the times of beginning and ending of the partial eclipse and its magnitude can be obtained for any point in the U.S.S.R. The second paper, by the same author, gives computations of the corpuscular eclipse, using four different velocities of particles, namely, 5000, 3000, 1600 and 800 km./sec., and assuming various sizes for the emitting surface of the sun, from a point to the full disk. A chart shows also the lines of totality for the optical ionospheric eclipse, at heights of 100, 150, 220, 300 and 500 km. A paper by B. Fessenkoff contains the plan of campaign as worked out by the Eclipse Commission of the Academy of Sciences, gives a general summing-up of recent experience in eclipse expeditions, and describes fairly fully the technique to be used in the astrophysical observations, which are concerned largely with the corona. Finally, P. Tverskoy discusses the geophysical problems to be investigated: mainly the radio exploration of high atmospheric levels in order to determine the relative importance of corpuscular and ultra-violet radiation there; secondly, the investigation of the effect on the solar radiation of the various parts of the atmosphere, including its lower layers; and lastly, an attack on the inverse problem, namely, how the eclipse affects physical conditions in the lower atmosphere. No detailed results have yet reached Great Britain, but a preliminary note (*J. Phys. U.S.S.R.*, 6, 1; 1942) gives ground for hope that much of the work planned was in fact carried out successfully.

Typhus in Palestine

ACCORDING to the *Lancet* of October 16, there have been 23 deaths from an outbreak of typhus during the past eight months in Palestine. The southern districts were chiefly affected, and the Department of Health has prepared special delousing units and portable showers for use in future cases. The disease is thought to have been introduced from neighbouring countries, especially Egypt. Murine typhus conveyed by rats is endemic in Palestine, but the present epidemic, which is more serious, is lice-borne and has not been seen in Palestine since the end of the War of 1914–18. A vaccine has been used with good effect, and a special laboratory for research and control of typhus has been opened under the charge of Prof. Kligler, head of the Department of Bacteriology and Hygiene (see also NATURE of November 27 p. 627).

South African Bored Stones

PART 4 of "The Bored Stones of Southern Africa by A. J. H. Goodwin (Univ. of Cape Town: Comm from the School of African Studies, Pt. 4. 2*s*.) ha recently reached Great Britain. It deals wit (*a*) the bored stones from the Cape of Good Hop and (*b*) certain elongated types. Together with th previous papers dealing with these special types o stone objects, this further statistical work will b very useful to the student of the Stone Age in Sout Africa.

University of Edinburgh

THE University of Edinburgh has received intima tion of a bequest by Dr. William Llewellyn Pryc Bevan, of Alton, Hants, of approximately £22,00 for the promotion of the teaching or the advance ment of medical science.

The Polish School of Medicine at the Universit of Edinburgh has added to its teaching staff Pro Maria Gutowska (medicine) and Dr. A. Jablonsk (natural philosophy).

Announcements

THE Committee of Privy Council for Medic Research has allowed amendments to the charter the Medical Research Council, simplifying the rul governing the retirement of members of the latt body and increasing the number of members by on By further Orders of the Committee of Privy Counci made after consultation with the president of th Royal Society and with the Medical Research Counci Prof. L. J. Witts, Nuffield professor of clinic medicine in the University of Oxford, and Prof. J. Learmonth, surgeon to H.M. Medical Household i Scotland, professor of surgery in the University Edinburgh, and surgeon-in-ordinary, Edinburg Royal Infirmary, have been appointed to be membe of the Medical Research Council.

THE Finney-Howell Research Foundation, Inc announces that all applications for fellowships f next year must be filed in the office of the Foundatio 1211 Cathedral Street, Baltimore, Maryland, January 1, 1944. This Foundation was provided f in the will of the late Dr. George Walker of Baltimo for the support of "research work into the cause causes and the treatment of cancer". Fellowshi carrying an annual stipend of 2,000 dollars ar awarded for the period of one year, with the poss bility of renewal up to three years.

DR. F. W. EDRIDGE-GREEN has pointed out th it is incorrect to attribute to Theodor Engelman the discovery of the cones and pigment cells of th retina (NATURE, Nov. 13, p. 560). Engelmann's mo important work was the discovery of the movemen of Deiter's cells and the pigment cells of the retir under the influence of light. Kölliker described th rods and cones of the retina in 1854.

Vitamin P-Deficiency in Guinea Pigs

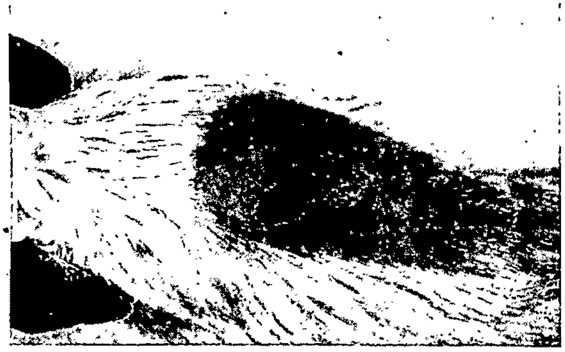
THE existence of vitamin P was first postulated by Szent-Györgyi and his colleagues[1,2] in 1935 and 1936. Other workers have since failed to substantiate their original conclusions[3,4]. However, so far as guinea pigs are concerned, Zacho[5] and Bacharach[6] have obtained considerable evidence that vitamin P deficiency is a reality. The fall in capillary resistance obtained by Bacharach and his co-workers[6,7] is small, but they have been able to show a statistically significant difference between the capillary fragility of the normal and the P-deficient guinea pig.

By taking a different end-point from that used by Bacharach in estimating capillary fragility in guinea pigs, I have obtained striking falls in capillary resistance and correspondingly large rises upon administration of citrin.

The technique used was fundamentally the same as that used by Bacharach[6], with the following differences. The suction cup was 20 mm. in diameter. It was placed on the shaven Vaselined skin of the animal and the pressure rapidly reduced to the desired level. It was left at this level for ten seconds and then released. The cup was removed and the skin examined for petechiæ. The capillary resistance was taken to be the negative pressure at which so many petechiæ developed that the area where the suction was applied became uniformly reddish-purple in colour; in other words, a hæmatoma was produced. Various sections of skin were tested until a positive result was obtained.

A total of 54 guinea pigs has been placed on the scorbutogenic diet used by Bourne[8] and each animal given 10 mgm. per day of vitamin C by mouth (Bacharach gave 5 mgm.). Their capillary resistances were taken on the day they were placed on the scorbutic diet, and in most cases at weekly intervals afterwards. In 30 normal animals no hæmatoma could be produced at 560 mm. mercury or more negative pressure. In the remaining 24 animals a hæmatoma was produced at negative pressures varying between 460 and 560 mm. of mercury.

The capillary resistance of individual animals took varying times to fall. The longest time for it to fall was eight weeks and the shortest time three weeks. The capillary resistance fell in all cases by at least 50 per cent and in some cases by more.



HÆMATOMA PRODUCED BY A NEGATIVE PRESSURE OF 310 MM. OF MERCURY IN A *P*-DEFICIENT GUINEA PIG. FIVE WEEKS PREVIOUSLY A NEGATIVE PRESSURE OF 560 MM. MERCURY HAD FAILED TO PRODUCE ANY EFFECT IN THIS ANIMAL.

Fifteen of these animals after the fall of capillary resistance had occurred were given five doses of 10 mgm. of citrin over a period of six days, and the capillary resistance was taken again on the seventh day after the test dosing began. Rises of from 60 per cent to more than 100 per cent took place in the capillary resistance. In those animals in which citrin was not given, the capillary resistance remained at a low level. After a few weeks, however, there was a slight rise in some of the animals, but it did not in any case amount to more than 20 per cent.

The actual figures obtained from these fifteen animals are shown below:

Normals (mm. negative pressure)	After some weeks on P-deficient diet (mm. negative pressure)	After treatment with 10 mgm. citrin (5 daily doses) (mm. negative pressure)
610	410	>560
>610	260	410
>610	310	460
>610	310	410
>610	360	>560
>660	410	>560
560	310	>560
>560	360	510
610	310	>560
>610	310	460
>560	310	410
>610	360	>560
>610	410	>560
560	310	>560
460	210	360

Such figures scarcely need statistical analysis, but as a matter of interest this has been done. It is difficult to compare figures such as >560 and >660 with other data, but by multiplying the reciprocal of each pressure by 1,000 a series of index figures has been obtained which it has been possible to subject to statistical examination. Figures bearing the prefix > are all given the index figure of '0'.

The application of this process to a few sample figures is shown below.

mm. pressure (P)	$1{,}000 \times 1/P$
>560	0
560	1·79
460	2·17
360	2·78
310	3·23

The average index figure for the 54 normal animals is 0·8050 ± 0·1250; that for the 54 P-deficient is 3·1810 ± 0·0880; that for the 15 P-deficient and citrin-treated animals is 1·0930 ± 0·3200.

If we compare these means by Fisher's '*t*' test, we find that the differences between those for the normal and the P-deficient animals and for the P-deficient and citrin-treated animals are highly significant. The means for the citrin-treated and the normal animals do not, however, differ significantly from each other.

The capillary resistance of a guinea pig on a scorbutic diet but receiving 10 mgm. per day of vitamin C will thus fall to a statistically lower level over a period of 3–8 weeks, and 5 daily doses of 10 mgm. citrin will bring the capillary resistance back to a level at which it is not statistically different from the normal. When the citrin treatment is discontinued, the animals sometimes die from a form of broncho-pneumonia, but in those which survive, the capillary resistance falls to its previous level over a period of 1–4 weeks.

It is difficult to resist the conclusion, in the face of these results coupled with those of Bacharach and Zacho, that vitamin P deficiency can exist, at least so far as guinea pigs are concerned, and that citrin contains a substance or substances (vitamin P), the effect of which is to return the capillary resistance to normal.

The pressures given were recorded on a spring manometer corrected against a mercury manometer.

I am indebted to Messrs. Roche Products for the supply of citrin and vitamin C used in these experiments.

Geoffrey H. Bourne.

Human Poliomyelitis in the Developing Chick Embryo

Several attempts by different authors[1] to propagate human poliomyelitis virus in the developing chick embryo have been entirely negative. In these experiments the technique employed was that elaborated by Burnet, the eggs being inoculated on the 10–12th day of incubation. Recently, however, I reported[2] successful transfer to, and serial passage in, chick embryos of mouse poliomyelitis virus (Theiler's virus). In conformity with the observation by Kligler and Bernkopf[3] on rabies virus, it was found that only young embryos—5–7 days old—were susceptible to infection. The virus was restricted to the central nervous system, and no lesions were detectable.

Although the conditions were most unfavourable for the continuation and extension of these experiments, in that the hatching eggs obtainable were of low quality, the mortality rate of the embryos being very high, and the supply of monkeys was depleted and could not be restored, it was considered worth while to try the same technique on human poliomyelitis virus. The result of the first attempt was promising, although not entirely convincing. As the experiments had to be discontinued for the time being, the present observation will, however, be reported.

The strain of virus used was the *L* strain, adapted to monkeys and of a uniformly high virulence. A 10 per cent suspension of glycerolated monkey cord was inoculated in 0·05 ml. amounts in four eggs on the sixth day of incubation. One embryo died on the day after inoculation; the remaining ones were all alive and showed normal development at the termination of the experiment. On the 10th day after inoculation the eggs were opened and the brains of the embryos harvested. 0·5 ml. of a pooled 10 per cent brain suspension was inoculated intracerebrally in a Rhesus monkey, an old animal with traces of a previous cage paralysis. Rectal temperature readings were taken daily for four weeks. With the exception of a slight fever during the first five days after inoculation, nothing abnormal was observed. The temperature of this animal was rather low, not exceeding 37·7° C. The result was considered negative. On the 70th day after inoculation, however, the animal displayed certain disturbances, irritability and slight tremor, and its fur was ruffled. On the following day the temperature was 38·4° C. and rose to 39·9° the day after. On the 73rd day the temperature fell to 36·4° in the evening and was 35·8° on the morning of the 74th day. Paresis of the legs became evident on the 71st day. On the 74th day a quadriplegia had developed. The animal was sacrificed. No gross lesions were observed at autopsy. Microscopic examination revealed typical lesions in the pons region, medulla oblongata, and all levels of the spinal cord, consisting of perivascular cuffing, scattered infiltration in the grey matter, and neuronophagia.

No other diagnosis than poliomyelitis presents itself. With the exception of this experiment, no work on human poliomyelitis had been carried out in the laboratory for more than six months previously. Accidental infection of the animal must, therefore, be considered most unlikely. In these circumstances the experiment gives suggestive evidence that human poliomyelitis virus can be propagated in the central nervous system of young chick embryos. The unusually long incubation period in back passage to monkey indicates that the concentration of virus remains on a low level.

Products Formed in Pyrethrin Concentrates during Storage

In the course of work on the structure of the pyrethrins, concentrates rich in pyrethrins I and II were stored in the dark for some months. It was then found that the concentrates were no longer completely soluble in petroleum ether and, surprisingly, that the insoluble residues showed a high 'apparent' pyrethrin content when assayed both by the Wilcoxon-Holaday and Seil methods[1], in spite of their low toxicity to house flies in comparison with freshly prepared pyrethrum extracts at equivalent concentrations. Thus two typical residues showed (Sample *A*) pyrethrin I, 13·5 per cent w/w, pyrethrin II, 64·7 per cent w/w (Wilcoxon-Holaday), and pyrethrin I, 15·1 per cent, pyrethrin II, 65·1 per cent (Seil), and (Sample *B*) pyrethrin I, 43·1 per cent, pyrethrin II, 7·5 per cent (Wilcoxon-Holaday), and pyrethrin I, 47·5 per cent, pyrethrin II, 7·2 per cent (Seil), yet 1 per cent solutions of these residues in acetone were less effective against house flies under exactly comparable conditions than a 0·1 per cent solution of pyrethrins in the same solvent made up from concentrates of the same type but freshly prepared. In addition, appreciable absorption of light was observable (in alcoholic solution) at the absorption maximum characteristic of the pyrethrins²; thus (*A*) showed $\lambda_{\text{max.}}$ 2310 A., $E^{1\%}_{1\text{cm.}}$ 144, whereas (*B*) showed $\lambda_{\text{max.}}$ 2280 A., $E^{1\%}_{1\text{cm.}}$ 495.

It has been shown³ that the light absorption of the pyrethrins is almost certainly due to a summation of the separate contributions of two isolated chromophores (*a*) a conjugated dienoid system in the pentadienyl side chain, and (*b*) an αβ-unsaturated ketonic grouping in the *cyclo*pentenolone ring. In view of hese data and the fact that the chemical methods of assay mentioned above depend, respectively, upon he properties of the carbonyl group and of the chrysanthemum mono- and di-carboxylic acids, it eems most reasonable to assume that the αβ-unsaturated ketonic grouping and the acidic fragments of the pyrethrin molecules remain unaltered in these esinous products but that the change—probably polymerization—involves the pentadienyl side chain. The accompanying great reduction in toxicity of such products, with retention of some degree of biological activity, would appear to be in accord with the conclusions of Staudinger and Ruzicka⁴ on the effect on toxicity of changes in the molecular structure of pyrethrins I and II and related synthetic compounds. Furthermore, it has been observed¹ that saturation of the side chain in the pyrethrin II molecule leads to a great decrease in both 'knock-down' and lethal effects.

Relation of Tea 'Fermentation' to Normal Respiration

IT is correct, as Roberts states in his communication¹, that I did not "repeat the conditions under which the Tocklai experiments were carried out". I attempted² to simulate injuries to tea leaf comparable with those caused during normal tea manufacture. Roberts, however, used an attachment which will grind nuts to a fine paste and thereby caused more structural damage to the leaf than I did with a mincing machine and far more than ever results from tea-rolling during manufacture. He attaches great importance to the shearing forces produced by his attachment because he believes that "such shearing forces are to be considered as responsible for the disorganization of respiratory processes which results in tea-fermentation"—even in the absence of visible cell damage. His own published results³, however, do not give support to that belief.

Roberts shows that two non-tanniferous tissues, *Tropæolum majus* and *Hibiscus rosasinensis*, have a carbon·dioxide output of 1·98 μl. and 1·6 μl. respectively per mgm. dry weight of tissue per hour, which when compared with the value 1·29 μl. found by Boysen Jenson⁴ in respiration experiments on *Tropæolum majus* shows them to be of the same order. There is no question of polyphenol oxidation in these tissues, and since the *R.Q.* is very near unity the carbon dioxide output is presumably all due to normal respiration.

As Roberts's experiment demonstrates that very severe mincing plus the shearing effects produced by the attachment do not completely disorganize the respiratory process in *T. majus* and *H. rosasinensis*, why must we *assume* that they will have a different effect on tea leaf? If, as I submit, respiratory activity persists in portions of crushed tissue (as caused by normal tea-rolling) independent of any fermentation proceeding at the same time, there appears no need to build up an elaborate hypothesis to account for the carbon dioxide produced during the two co-existing processes.

The higher carbon dioxide output from other tissues (including tea) of itself proves nothing when the wide variation of respiration intensities in different plant species is borne in mind.

Discussing my results with washed and unwashed tissue-mince, Roberts has stated that it is by no means unlikely that in the unwashed tissues the carbon dioxide produced (1) by carbohydrate oxidation in the damaged cells with *o*-quinones as H-acceptors and (2) normal respiration in the undamaged cells inhibited by free (oxidized ?) polyphenols are together equal to the respiration of the washed undamaged tissues now uninhibited by polyphenols. This would mean that the carbon dioxide produced by the *o*-quinone reaction always balanced the inhibition in normal respiration. Such a coincidence in quantitative results is, however, scarcely to be expected in a complex system such as minced tea leaf.

Darwin and 'Water-Bloom'

SOME years ago, I described the formation of red 'water-bloom' in the seas round Cape Peninsular, by myriads of the ciliate *Mesodinium rubrum* Lohmann¹. I had been unable to find references (in the literature available on the spot) to ciliates as a cause of this phenomenon, though 'water-bloom' caused by various other micro-organisms was well known in many localities. A reply from Prof. O. Paulsen² showed that formation of red 'water-bloom' due to Mesodinium had been seen by him at Iceland thirty years earlier. The Danish publication was out of my reach at the time, but I ought not to have missed the astoundingly accurate, detailed description of Mesodinium forming red water made by Darwin³ some fifty years earlier still, before Mesodinium had in fact been named. No one who has examined swarming Mesodinium alive could have any doubt as to the identity of the organisms described by Darwin, and it would be very hard to improve his verbal description.

The red water was encountered by H.M.S. *Beagle* a little to the south of Valparaiso, near the southern boundary of the Peru coastal current, under meteorological conditions precisely the same as those we found to accompany red water at the Cape. My colleague, the late E. R. Gunther, has described discoloration of the sea by living organisms in the Peru coastal current with references up to 1936 in great detail[4], but he also missed this point of Darwin's, and for that I am to blame, for I was trying to help him with microplankton references while he was engaged with other aspects of the work. It is interesting to note further that a second type of 'water-bloom' described by Darwin[3] near the Galapagos tallies almost equally well with Gunther's[4] observation of a yellow patch ". . . due to a swarm of a colonial radiolarian, probably Collosphaera . . . some 180–200 miles off Punta Aguja".

The peculiar conditions resulting in the formation of bottom deposits emitting hydrogen sulphide found off the south-west African coast, farther north than "Discovery Investigations" have proceeded in detail, and described by Copenhagen[5], are analogous to those observed in parts of the Peru coastal current. It will be very interesting to learn whether 'water-bloom' phenomena also extend northwards along that coast so far as the Walfisch Bay area.

Mesodinium is now known to have been a cause of red 'water-bloom' off central Chile in winter[3], in Seydis Fjord, Iceland, in summer[6], off Cape Peninsular in autumn and winter[1], and off British Columbia[7]. There may be other records that elude me under present conditions.

The influence of 'water-bloom' phenomena upon animals of economic importance is at times profound, so it is certain that more research upon them will be needed in the future. It is therefore pleasant to find the origins of scientific treatment of the subject in the work of Darwin, for he must always rank (in the minds of naturalists who ply their trade in deep waters) among the greatest field-workers of all time, whatever his later fame depended upon.

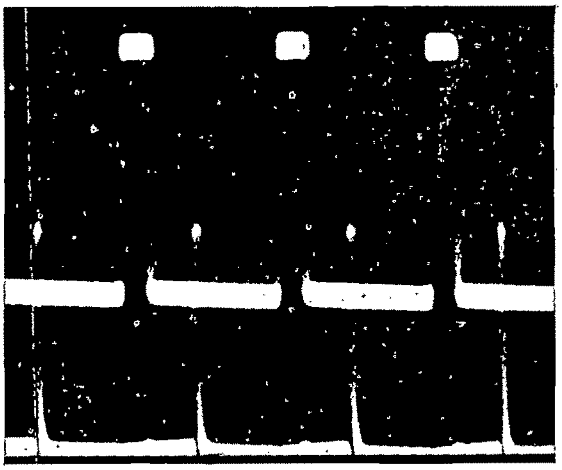
An Oscillographic Method for the Determination of the Velocity of Sound

METHODS of measuring the velocity of sound in air, using the cathode ray oscillograph, have been described by Wold and Stephenson[1], Colwell and others[2,3,4] and by Patchett[5]. Only one precise determination by an oscillographic method has been attempted[4], and the results in this case are of doubtful value since, for example, the influence of humidity and carbon dioxide content of the air have been ignored.



UPPER TRACE—MICROPHONE PULSES. LOWER TRACE—LOUD-SPEAKER PULSES.

The method to which this communication refers is similar in principle to that used by Colwell, but is considered to be capable of greater accuracy. Sound from a loud-speaker connected to an audio-frequency oscillator is picked up by a microphone, which moves on rails perpendicular to the plane of the speaker. The potential difference developed by the microphone is amplified and operated on by pulse-shaping circuits which change its sinusoidal waveform into a series of short rectangular pulses. The output from this arrangement is used to deflect one beam of a double-beam oscillograph. If the microphone is moved along its rails, the pulses travel across the screen and the distance between positions of the microphone at which corresponding points of successive pulses coincide with an arbitrary reference mark is equal to the wave-length of sound at the frequency employed. The reference mark is obtained by connecting the loud-speaker terminals to a separate pulsing circuit, using the output to deflect the second beam of the oscillograph. The trace then has the appearance shown in the accompanying illustration. As the microphone is moved, the upper set of pulses travels across the screen, while the lower series remains stationary. The frequency of the oscillator is checked against that of a standard electrically maintained tuning fork, by continuous observation and adjustment of a Lissajous figure on an auxiliary oscillograph. Frequencies between 4,000 c.s. and 5,000 c.s. have been used, and in this range twenty or thirty values for the wave-length may be obtained by moving the microphone through a distance of two metres.

Preliminary experiments give reason to believe that this arrangement, with minor modifications, may be used for very precise determinations of the velocity of sound in various media. Further research along these lines is in progress.

Flow of Visco-Elastic Materials in Capillaries

In a previous communication[1] an error in pressure measurement was pointed out, which might lead to spurious results in measuring the viscosity of certain anomalous liquids. Reference was also made to viscosity determinations recently carried out on rubber solutions and the like, using a viscometer in which the true pressure-drop along the capillary was measured directly. The measurements indicated the existence of an end effect, the ratio of the length, L, to the diameter, D, of the capillary, being a significant factor. A typical family of flow curves for one rubber solution, plotted in the conventional manner, is indicated in Fig. 1. These clearly show that if the L/D ratio is sufficiently large, the curves approximate closely to a line which is independent of capillary bore. Smaller L/D ratios give curves diverging from this, indicating a higher apparent viscosity, the divergence increasing as L/D decreases. These curves emphasize the importance of using long tubes, particularly at high stresses, if the results are to be assumed to apply to an equilibrium condition.

This effect, in which long capillaries indicate lower apparent viscosities than short ones, has already been observed for rubber solutions and other visco-elastic materials[2,3]. In order to explain this, we may suppose the material on entering the tube to be 'stretched', or elastically deformed, until equilibrium is reached for the particular shearing stress applied, the material then flowing through the remainder of the tube in this state. For very long tubes, this 'elastic end effect' would tend to become negligible in comparison with the overall length, and flow curves would then give a true, or nearly true, representation of the behaviour of the material under the particular conditions. As the tube length decreases, the end effect becomes large in proportion to the total length, and we should expect a progressive departure from the limiting curve, such as that illustrated in Fig. 1. We should also expect this end effect to increase in magnitude with increasing stress and this would, in turn, accentuate the difference in the flow curves between capillaries of differing L/D ratio. Fig. 1 clearly shows this effect with increasing stress, and further, this end 'correction' deduced from the flow curves and expressed in tube diameters is actually *proportional* to shearing stress. A similar effect ought to occur if the concentration were increased, and this is, in fact, found experimentally. Curves similar to those shown have also been obtained with mineral oils containing metallic soaps.

When the liquid emerges from the capillary it is still elastically deformed and will consequently tend to return to its former 'unstretched' condition. This results in a swelling of the emergent column of liquid which is easily observed, as Fig. 2 shows[4]. It is evident that elastic recovery commences at the actual capillary end. As with the 'elastic end effect', it is to be expected that this swelling will increase both with increasing stress and increasing concentration, and this is found to be so for the materials in question. Here again we find that elastic recovery is *proportional* to stress.

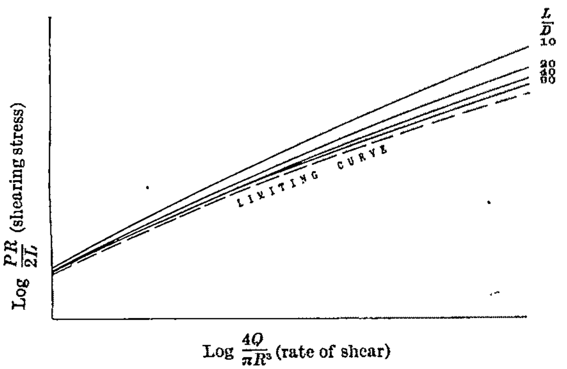

Fig. 1.

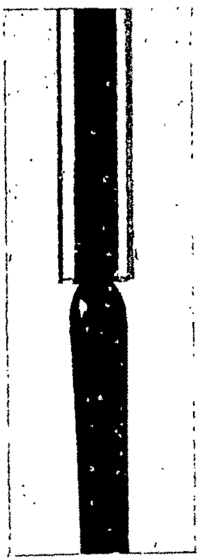

Fig. 2.

In other words, the 'elastic end effect' which results in a difference in the flow curves, and the swelling of the emergent column of liquid, are related, and either should give a measure of the elastic property of the material.

High-Angle Edge Flaking of Flint

The recent communications on this subject by Mr. J. Reid Moir[1] and Mr. Alfred S. Barnes[2] show that the old battle over the artificial or natural origin of eoliths is on again. Space does not permit quotation of the opinions on both sides of the original argument starting in about 1912, but it seems to me that, among other things, Moir has proved two important points: (1) that it is possible for modern man to take high-angle flakes off flint cores; and (2) that among other criteria of intentional work on primitive stone artefacts one of the most important is that the edge flakes are taken off in an adjacent series, thus giving an edge of desired shape[3].

As Barnes points out, use was sometimes made of steep flaking in palæolithic work; but he seems to think that primitive man was not likely to use this type of flaking to any great extent. From this he assumes that the frequency of its occurrence on supposed implements can be used as a criterion of their intentional or natural origin. This process of reasoning leads to the danger of arguing in a circle. In any event his analysis[4] of the use of steep flaking in certain palæolithic industries is misleading, as he omits the Aurignacian, in which special use was made of steep flaking, and the Magdalenian, where the removal of flakes from cores can only be done by steep flaking relative to the core.

Now if Moir's criterion is applied to the flaked flints which are claimed by Barnes to have been done by some natural means, especially those from Central

France, Kent and East Anglia, the flaking on a great many of the specimens is seen to be intentional. I have had the opportunity of examining a very large number of specimens from the Upper Miocene (or Lower Pliocene) of Central France, and the systematic edge flaking on most of these seems to me definitely intentional. I have not been able to examine a large collection of Harrisonian eoliths from Kent, but such as I have seen appear to have the same systematic series of flakes. The sub-Crag specimens present rather a different problem, including as they do primitive palæolithic types, but those among them which were partly made by steep flaking again show series of edge flakes which are too systematic to have been done by natural means.

As regards modern experiment, I have had the opportunity of examining specimens of steep flaking done by Mr. Reid Moir, and of watching him remove these flakes with a hammer stone. I have also succeeded in doing the same type of flaking myself, and am convinced that it is not very difficult. It is also relatively easy to take off an adjacent series of such flakes so as to produce an edge of desired shape. My own experiments in making and using various types of stone implements are as yet incomplete, but according to my experience eolithic edge-work is fairly easy to do both on flint and on Bunter pebbles (the latter approximating to Darmsden and Soan types); also various pre-palæolithic types, including rostro-carinates, can be made with practice, involving some use of steep flaking. Experimental copying of Aurignacian and Magdalenian types also shows that flaking at about 90° is necessary for removal of the flakes from the cores. It is my experience that copies of eolithic and pre-palæolithic forms can be used for cutting wood, though they are not so efficient as copies of Acheulean or Clactonian types; I have also found that those made of quartzite do not take as keen an edge as those made of flint, and are therefore less efficient.

It seems to me that recognition of intentional work on flaked stones claimed as primitive implements involves two definite questions: (1) *Could* they have been made intentionally? (2) If so, *could* they have been used for any purpose? As modern man *can* make copies of eolithic and pre-palæolithic types, the answer to question (1) is that these types *could* certainly have been made by primitive man. As such implements can be used, for example, for cutting wood, there would have been some purpose in making the originals. If this is so, the question of a natural origin scarcely arises, and those who may believe in the possibility of such a process will have to explain why certain restricted eolithic forms were made naturally at an Upper Miocene or Lower Pliocene date, to be followed by more diverse and advanced forms in Pliocene and Lower Pleistocene times.

D. F. W. Baden-Powell.

[1] Moir, J. Reid, Nature, 152, 78 (1943).
[2] Barnes, A. S., Nature, 152, 477 (1943).
[3] Moir, J. Reid, "Pre-Palaeolithic Man", p. 15.
[4] Barnes, A. S., *Amer. Anthrop.*, 41, 110 (1939).

In his letter in Nature of October 23, Mr. A. S. Barnes says: "The high proportion of high-angle scars in the Tertiary flints . . . suggests that the Tertiary flaking was due to soil movement under pressure arising from solifluxion, foundering, or ice-action". But I think most geologists would agree that these three factors (or at any rate the first and third) were far more active in Pleistocene than in Tertiary times. Why have they failed to produce any comparable effects in the later period? It is an old question, but not less cogent on that account.

Mr. Barnes ignores the evidence of his own figures[1], that there is a connexion between the number of these high-angle scars and the age of the implements concerned; for we pass in percentage from 0 in Solutrean, through 1 in Mousterian, and 5 in Early Acheulean, to 18 in "Chelléen et Préchelléen" (Warren Hill). It is, of course, impossible to construct an accurate graph from these figures, since we do not know the time-intervals involved; but the curve is obviously rising rapidly as we pass from the later and more skilled to the older and rougher work, and it seems by no means impossible that it might rise to 60 or even 70 per cent by the time we reach the Kentish plateau.

It seems unfortunate in this connexion that Mr. Barnes has omitted all mention of the Cromerian flints, and of the "Prechellean" implements of the Zambezi River[2]; for the former might supply some intermediate stages, while the latter are free from all ice-action, and (so far as one can judge by the contours) from any powerful effects of solifluxion and foundering. Admittedly our knowledge of these Zambezi implements is still very imperfect; but until we have fuller information about them, any conclusion along the lines of Mr. Barnes's arguments would seem to be premature.

Radio Fade-Out on February 10, 1943

O. E. H. Rydbeck, Chalmers Institute of Technology, Gothenburg, in Nature of June 19, 1943, has requested information about magnetic disturbances on February 10, 1943. At the Magnetic Observatory, Hermanus, where the magnetogram sensitivities were: H, 2·32 γ/mm.; D, 0·534 ′/mm. = 2·20 γ/mm.; Z, 3·69 γ/mm.; disturbances were recorded and published in *Terrestrial Magnetism and Atmospheric Electricity* (June 1943).

Micropulsations, which were little more than a broadening of the D trace, appeared at 07h. 47m. G.M.T., February 10. About three hours later disturbances were recorded on all traces, the D disturbance being greater than the H disturbance, which at this Observatory is characteristic of magnetic disturbances at the time of a radio fade-out. The beginning of the disturbance was not sharply defined. On the H trace the beginning was at about 09h. 45m. G.M.T. and on the D and Z traces at about 09h. 43m. G.M.T. February 10. Seventeen hours later there were abrupt changes indicating the beginning of a magnetic storm. A time interval of 17 hours would indicate a speed of about 1,500 miles per second for the transmission of impulses from the sun.

MEDAL AWARDS FOR 1943 OF THE ROYAL SOCIETY[*]

Copley Medal

THE Copley Medal is awarded to Sir Joseph Barcroft, emeritus professor of physiology in the University of Cambridge, and now the head of a research unit established there in animal physiology.

The researches on the respiratory function of the blood, in respect of which this highest of the distinctions in the Society's gift is awarded this year, have occupied a central position in Barcroft's life-work. Their record is one of steady purpose and unbroken progress over a period of some forty-five years. At Barcroft's own hands, and at those of the long and very distinguished succession of collaborators who have been associated with him, these researches have had many important extensions into neighbouring fields of biological inquiry; they have played a great part n a wide range of recent advances in physiological, biochemical and medical science throughout the world; and they have been an important factor in the creation of a scientific basis for the study of manifold human activities, of work and of play, in peace and in war.

As a newly graduated student at Cambridge, Barcroft seems to have seen already the significance of the problem to which he was thus to devote so many years of fruitful investigation, recognizing the respiratory function of the blood as a condition of the life and a measure of the metabolic activity of every part of the body of the higher animals. With a cumbrous equipment of pumps and their accessories, alone available for such determinations in those early days, he applied himself with great determination and ingenuity to a study of the changes of oxidative metabolism which accompany secretory activity in the salivary gland. From that beginning his researches grew and developed in logical sequence, including studies of oxidative metabolism in relation to specific activity in the kidneys, the liver, the muscles and other organs, with various excursions to deal with corollaries from this central theme.

Early in the series came Barcroft's invention of a comparative manometric method, which effected a revolutionary simplification of the technical operations involved in obtaining the data required. The same method enabled him, in due course, to make his classical redeterminations of the relation between the pressure of oxygen and its combination with, or release from, blood or solutions of hæmoglobin, and of the effects of varying conditions on the graphs representing that relation. The principle of this method, as employed either in Barcroft's own original apparatus, or in the more delicate micrometric form which Warburg later introduced, has passed into standard use in every laboratory of functional biology throughout the world, for measuring rates of respiratory metabolism in surviving samples of living tissues and of various chemical changes due to artificial enzyme systems. Barcroft and his companions in research have used it, in expeditions which he led to Monte Rosa and to the Andes, to study the modifications of man's physiology by life at high ltitudes and at low oxygen tensions, providing knowledge which to-day has an ever more urgent application to the problems of human flight; and in two successive wars Barcroft himself has used the knowledge built up and the skill acquired in his peaceful researches to the direct aid of his country in its need.

Studies of the differences between the respiratory functions of the blood in fœtal and independent life led Barcroft, with a characteristic readiness to follow the lead of natural interest, into a neighbouring field of inquiry, to a more general study of the physiology of mammalian fœtus, and thus to the results which he reviewed in the Croonian Lecture of 1935 on "Fœtal Respiration". His need, for that purpose, to make observations on larger animal types, such as the sheep, led again to a wider interest in the physiology of farm animals, and so to the new enterprise for which his more recent research appointment provides welcome opportunity.

In a preface to his book, Joseph Barcroft finds a connexion between what he learned in sailing boats and what he has done in research. We may think of him, perhaps, as one whose instinct and aptitude have led him to venture as an explorer beyond visible horizons, rather than to sound remoter depths of theory in seas already known. Such a thought would place him in a long tradition of this Society, in company with such great students of the respiratory function as Boyle, Hooke, Mayow and Lower among our earliest fellows, and, of those who over the centuries have received this Copley Medal, with Stephen Hales and Joseph Priestley and, most intimately of all, with John Scott Haldane, who received it nine years ago. Barcroft's work, like Haldane's, of high scientific merit in itself, has extended its influence far beyond the laboratory over a wide range of the beneficent and creative activities of mankind at peace, and now again, for the last time let us hope, to those imposed by the dire compulsion of war. We rejoice to know that in him the hunger for knowledge is still unsatisfied, and that he is still sailing his craft towards new horizons.

Royal Medals

A Royal Medal is awarded to Sir Harold Spencer Jones, Astronomer Royal for England, in recognition of his determination of the solar parallax and of other fundamental astronomical constants.

Much of the earlier work of Spencer Jones was devoted to the discussion of certain fundamental astronomical constants, and in this field of work he was long ago recognized as a leading authority. At the meeting of the International Astronomical Union held at Leyden in 1928, a Solar Parallax Commission was appointed, with Spencer Jones as president, in preparation for the favourable opposition of the minor planet Eros in 1931.

The planning and co-ordination of the enterprise of redetermining the solar parallax, in which twenty-four observatories took part, fell mainly upon him, and he was entirely responsible for the assemblage of the material, and for the derivation of the results. It is to be noted also that the Cape Observatory, of which he was then director, made the greatest contribution to the observational material. The circumstances of the opposition favoured southern observatories, and the plates obtained at the Cape contributed more weight than those from all the other observatories combined.

The whole task of reduction of the observations was carried out under Spencer Jones's supervision, and the memoir which contains the complete discussion of the material and the results obtained from it (*Mem. Roy. Astro. Soc.*, vol. 66, part 2; 1941) is a masterly exposition of the whole subject of the investigation of solar parallax and of the interrelated constants.

---

[*] Remarks made by Sir Henry Dale in presenting the awards on November 30.

The solar parallax finally derived is given as 8·790 ± 0·001, as compared with the value of 8·806 ± 0·004 obtained by A. R. Hinks at the preceding opposition of Eros in 1900–1. Spencer Jones found complete agreement between the results derived separately from northern and southern observatories, or from right ascensions and declinations separately, or from photographic and photovisual telescopes, or from primary and secondary stars, as well as from four successive periods of time during the opposition. No matter how the material was subdivided, no substantial difference could be found in the value of the solar parallax derived. There is thus every reason to think that systematic error has been eliminated, and that the probable error of 0·001 truly represents the high degree of accuracy of the final result. Therewith we are given a new estimate of the earth's distance from the sun, which is likely to stand without revision for many years. These observations on Eros also yielded a new estimate of the mass of the moon, which has less than half the probable error of the previous determination.

The modification of the previously accepted value of the solar parallax affects the estimates of other astronomical and geophysical constants. Spencer Jones's work is enhanced by his discussion and general adjustment of the values of all these interrelated constants, and in this he makes a substantial new contribution to the problem to which so much of his earlier work was devoted.

A Royal Medal is awarded to Dr. E. B. Bailey, director of the Geological Survey of Great Britain, in recognition of his contributions to the knowledge of mountain structure and his studies on the tectonics of vulcanism.

The number, range, and importance of Bailey's contributions to geology can have few parallels in the history of this science in Britain. It is only necessary to review his major publications to recognize the solid achievements that stand to his credit in the diverse fields of petrography, tectonics, stratigraphy, glaciology and physiography. But it is more particularly by his outstanding contributions to the knowledge of mountain structure and on the tectonics of vulcanism that he is to-day acknowledged internationally as a leader.

His work on mountain structure is contained in a long series of memoirs on the non-fossiliferous schists of the Southern Highlands of Scotland. These studies, prosecuted far across country and presented in a brilliant synthesis of the structure over a large part of the south-west and central Grampians, mark a great advance in the field of mountain tectonics and have provided a notable stimulus to research on Highland geology.

Bailey's now classic researches undertaken in conjunction with Clough and Maufe on the Devonian volcanic cauldron subsidence of Glen Coe, and his early work on the petrology and classification of the Carboniferous volcanic rocks of the midland valley of Scotland, were stepping-stones to the immense task which he set himself in later years in the island of Mull. It is these investigations which have revolutionized our knowledge of the inner structure of British volcanoes; for to them we owe the recognition of ring dykes and ring complexes and the conception of igneous intrusion by ring fracture stoping.

Bailey's insatiable zest for scientific research has led him into other fields, and among notable contributions to Scottish geology must be reckoned the work he carried out with Kendall on the glaciation of East Lothian and the additions he made to the knowledge of the physical geography of Millstone Grit, Kimmeridgian and Cretaceous times. Farther afield his studies have dwelt on the tectonics of the Pennsylvania Piedmont and on the seismic origin of submarine canyons of the continental slope: and he has shown the importance to be ascribed to submarine landslips in the past record of the rocks, notably in the Palæozoic succession of Quebec.

Throughout a long and active career Bailey, by his enthusiasm, his powers of observation and his interpretative insight, has rendered splendid service to the science of geology, and his record of achievement is unsurpassed among living British geologists

Davy Medal

The Davy Medal is awarded to Prof. I. M. Heilbron, professor of organic chemistry at the Imperia College of Science and Technology, in recognition of his many notable contributions to organic chemistry especially to the chemistry of natural products of physiological importance.

After some early researches dealing with the chemistry of the coumarins, chromanes and benzopyrylium salts, Heilbron made his first really important contribution by his well-known investigation on the remarkable hydrocarbon, squalene, which occurs in certain fish oils. Almost simultaneously he established the structures of batyl and selachy alcohols. His interest in fish oils being thus aroused he next turned his attention to vitamin A. He attacked this problem in the first instance by the use of the spectrograph with the collaboration of Morton, who was thereby led to develop methods for the quantitative estimation of this vitamin, which hav since proved invaluable. Heilbron's contribution to the chemistry of vitamin A earned him an international reputation, and later led to the recognition of vitamin A_2. He has attacked also the difficul problem of the synthesis of vitamin A and, although it has not yet reached its objective, his work in thi direction has raised many points of great interes and importance.

Heilbron has also made notable contributions to our knowledge of the sterols and triterpenes. In this field, following pioneering work on the structure of ergosterol, he provided an elegant proof of the structure of vitamin D_2 (calciferol) and has elucidated the structures of lumisterol, fucosterol and, mor recently, zymosterol. In the triterpene field his most notable contribution has been his discovery of th key alcohol, basseol, which, in view of its facil conversion into β-amyrin, seems likely to play a significant part in the classification of triterpen chemistry.

The outbreak of war interrupted Heilbron's projected study of the lipochromes and sterols of the algal classes, a study likely to be of importance not only to the chemist but also to the botanist, for whom it may provide a new basis of classification. A résumé of this work formed the subject of a Hug Müller lecture to the Chemical Society. Britis chemists are indebted to Heilbron more than to an other chemist for the introduction into Great Britain of the most refined new techniques. He has used extensively in his researches chromatographic absorption, microanalysis and high-vacuum distillation, while he was probably the first to recognize the potentialities of absorption spectra as a research tool. His influence has thus spread far beyond the circle of the many research chemists trained in his laboratories.

Sylvester Medal

The Sylvester Medal is awarded to Prof. J. E. Littlewood, Rouse-Ball professor of mathematics in the University of Cambridge, in recognition of his mathematical discoveries.

Among mathematicians, the name of Littlewood will always be associated with that of G. H. Hardy for the wonderful example of perfect teamwork in their fashioning of a new and rare instrument of mathematical precision during the second and third decades of the twentieth century. Into the theory of numbers, that subject where problems are so easy to state but so hard to prove, an entirely new spirit was nfused when the methods of analysis were brought to bear upon it. The credit for attaining the highest results, for perfecting the methods, and for inspiring an enthusiastic following among so many of the noblest mathematicians at home and abroad, all belongs to Hardy and to Littlewood. Littlewood, who is by age the junior in this remarkable partnership, brought his own magnificent contribution, as Hardy himself has wholeheartedly testified. Littlewood, on Hardy's own estimate, is the finest mathematician he has ever known. He was the man most likely to storm and smash a really deep and formidable problem: there was no one else who could command such a combination of insight, technique, and power.

Littlewood's work covers a wide field of pure mathematics, extending from his fundamental discoveries in the realm of integral functions (1908) up o the present date. It was a happy event when Ramanujan, with his intuitive genius, proposed problems that brought out the fullest powers and skill of Littlewood and Hardy and their analytical heories. We can have no doubt that there is a peculiar fitness in the immediate succession of Littlewood to Hardy in this triennial award of the Sylvester Medal for mathematical research.

Hughes Medal

The Hughes Medal is awarded to Prof. M. L. E. Oliphant, Poynting professor of physics in the University of Birmingham, in recognition of his work on nuclear physics and mastery of modern methods of generating and applying high potentials.

Oliphant, initially under the general guidance of Rutherford, has made fundamental advances in the ield of nuclear disintegration. With the aid of pecially designed apparatus he has produced intense beams of protons and of the nuclei of heavy hydrogen, with homogeneous energy, the study of the reactions of which with light nuclei has proved very fruitful. The intensity of the beam which Oliphant has obtained has allowed effects to be produced at much lower voltages than had hitherto been available. The theoretically important disruption of the lithium nucleus has been investigated with particular care. In this connexion a separation of the two lithium isotopes was first effected, so that they could be separately studied, with a consequent greater certainty as to the reactions.

In Oliphant's researches the energy liberated in certain nuclear reactions has been measured to a remarkably high degree of accuracy, and the laws of conservation of mass-energy and of momentum have been verified. This is a matter of great importance for the understanding of nuclear reactions, and has also enabled the masses of the light atoms to be calculated very precisely.

As a result of work carried out by Oliphant with Harteck, on the bombardment of the nuclei of heavy hydrogen with like nuclei, two new light isotopes have been discovered, one of hydrogen and one of helium, both of mass number 3. The nuclear reactions of beryllium and of boron have also been carefully investigated.

In the published accounts of the work Oliphant's name has often been associated with that of others, including Rutherford, but there is no doubt that he was responsible for the very specialized experimental technique, as well as for other contributions to the collaborative enterprise. Oliphant has been particularly successful in the design of apparatus. Besides that required for the researches to which reference has been made, he has been responsible for the development of the two-million-volt installation at Cambridge. During the War he has successfully carried out work of great importance. His fine record of achievement is fittingly recognized by the award of the Hughes Medal for "original discovery in the Physical Sciences, particularly electricity and magnetism or their applications".

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, December 4

GEOLOGISTS' ASSOCIATION (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. Alan Wood: "Basic English and its use in Geology" and "Organs of Reproduction in the *Solenoporaceæ*".

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the SHEFFIELD SOCIETY OF ENGINEERS AND METALLURGISTS and the IRON AND STEEL INSTITUTE) (at the Royal Victoria Station Hotel, Sheffield), at 2.30 p.m.—Discussion on the Fourth Report of the Oxygen Sub-Committee.

Monday, December 6

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. W. A. Robertson: "Timber—the Minor Products" (Cantor Lectures, 3).

SOCIETY OF CHEMICAL INDUSTRY (LONDON SECTION) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Prof. W. E. S. Turner, F.R.S.: "Glass for Use in the Chemical Industry"; Mr. I. C. P. Smith: "Sintered Glassware—Manufacture and Uses".

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 8 p.m.—"Geography of Post-War Air Routes" (Discussion to be opened by Lieut.-Colonel Lord Brabazon; and Film, "Singapore to London").

Tuesday, December 7

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Mr. L. Bohdanowicz: "The Polish Tartars".

INSTITUTION OF CIVIL ENGINEERS (RAILWAY ENGINEERING DIVISION) (at Great George Street, Westminster, London, S.W.1), at 5 p.m.—Mr. H. R. Reynolds: "Soil Mechanics and the Railway Engineer"; Mr. M. F. Barbey: "Some Soil Mechanics Problems on the L.M.S. Railway".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. J. C. Drummond: "Food Problems of the Post-War Years", 3: "Food Technology".*

Wednesday, December 8

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. A. C. Bossom, M.P.: "Some Modern Methods of Construction Practised in America".

INSTITUTE OF FUEL (at the Connaught Rooms, Great Queen Street, Kingsway, London, W.C.2), at 2.30 p.m.—Major-General K. C. Appleyard: "The Production and Use of Open-Cast Coal".

Thursday, December 9

Royal Institution (at 21 Albemarle Street, London, W.1); at 2.30 p.m.—Prof. W. Perceval Yetts: "Links between Ancient China and the West: a Study of Exchanges in Material Culture", 3: "The Quest of the Superior Horse".*

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Mr. Arthur Mortimer: "The Ministry of Supply and its Relation to the Pharmaceutical Industry".

Friday, December 10

Royal Society of Arts (India and Burma Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. H. S. L. Polak: "India and American Opinion".

Oil and Colour Chemists' Association (Manchester Section) (at the Grand Hotel, Manchester), at 2.30 p.m.—Dr. V. G. Jolly: "The Progress of Paints and Painting".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 p.m.—Prof. H. W. Florey, F.R.S.: "Penicillin: its Development for Medical Uses".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. S. L. Smith: "A Survey of Plastics from the Viewpoint of the Mechanical Engineer": Mr. J. Lionel Daniels: "Moulding Plant for Plastics".

Institute of Physics (London and Home Counties' Branch) (at the British Institute of Radiology and Rontgen Society, 32 Welbeck Street, London, W.1), at 6 p.m.—Dr. E. H. Rayner: "The Electron Microscope".

Saturday, December 11

British Mycological Society (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 2 p.m.—Dr. S. P. Wiltshire: "The Organization of the Study of Systematic Mycology".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Histology in the Department of Physiology—The Registrar, King's College, Newcastle-upon-Tyne (December 8).

Engineer and Manager of the Edinburgh Electricity Corporation—The Town Clerk, City Chambers, Edinburgh (December 10).

Demonstrator (man or woman) **in the Chemistry Department**—The Warden and Secretary, London (Royal Free Hospital) School of Medicine for Women, 8 Hunter Street, Brunswick Square, London, W.C.1 (December 10).

City Engineer and Surveyor—The Town Clerk, Town Clerk's Office, St. Albans (endorsed 'City Engineer') (December 10).

Museum Curator—The Acting Clerk, Letchworth Urban District Council, Council Offices, Letchworth (December 11).

Woman Education Officer to teach Mathematics or Geography in African Boys' Secondary Schools or Teacher Training Schools, Tanganyika Territory—The Secretary (I.P.R./C.A.), Board of Education, Belgrave Square, London, S.W.1; or (for candidates in Scotland), The Secretary, Scottish Education Department, 29 St. Andrew Square, Edinburgh 2 (December 15).

Lecturer in High Voltage Engineering, and an **Assistant Lecturer in Mechanical Engineering**—The Registrar, College of Technology, Manchester 1 (December 31).

Superintendent to take charge of section of works in South Yorkshire engaged in the manufacture of Laminated Railway Springs—The Ministry of Labour and National Service, Appointments Office, The White Building, Fitzalan Square, Sheffield (quoting Reference No. A.O. 222).

Deputy Director of Tools under the Government of India—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Advertising Section, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.1949A).

Geologist in the Colonial Geological Survey Service, Nigeria (Reference No. F.1801), and a **Geologist** (temporary) under the Government of British Guiana (Reference No. F.1802)—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.).

Colonial Engineer and Surveyor-General for the Government of Dominica Public Works Department—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Advertising Section, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.821A).

Assistant Master or **Mistress** (temporary) **for Science and Mathematics**—The Principal, County Technical College, Stoke Park, Guildford.

Laboratory Assistant in the Electrical Engineering Department of the Municipal Technical College—The Director of Education, Education Offices, Oldham.

THE SOCIAL SCIENCES IN GREAT BRITAIN

ON what may perhaps be the eve of real measures of social reconstruction, the conclusions of the Committee on Scientific Research on Human Institutions appointed by the British Association are welcome. For if, as Mr. Churchill has said, it is a definite part of the duty and responsibility of the National Government to have its plans perfected in a vast and practical scheme to ensure food, work and homes after the War, research into the most efficient plans to form into such a scheme must be started forthwith. This research itself must be "vast and practical" and must integrate the work of natural and of social scientists. Representatives of both persuasions were members of the Committee, which consisted of Prof. P. Sargant Florence (chairman), Mr. L. J. F. Brimble (hon. secretary), Mr. H. J. Braunholtz, Prof. G. Catlin, Prof. C. H. Desch, Mr. A. Farquharson, Prof. J. C. Flugel, Prof. Morris Ginsberg, Prof. Lancelot Hogben, Dr. Julian Huxley, Prof. Harold Laski, with the President and General Officers of the British Association. Thus the Committee included a chemist, three biologists, a psychologist, an economist, an anthropologist, two sociologists and two political scientists. The detailed terms of reference point straight at the close connexion of social research and governmental plans. The committee was "to consider how the results of scientific research on human institutions and human needs and their interrelations can best be co-ordinated and brought to bear on the formation of public policy".

Any committee of the British Association, with its sections devoted both to the natural and to the social sciences, must start by dealing clearly with the differences and similarities in the research of these two groups of disciplines. The difference is seen in the fact that the recognized natural sciences, including even physical anthropology, do not deal with the contact of man with man. To study these essential contacts the report envisages a sociology dealing with types of human association and organization and their functioning through the "operation of law, morals and religion in society and of other forms of social sanctions and control, including the economic price mechanism".

But the similarities of the two groups of sciences are greater than is usually assumed both in the method employed and in the material it is employed upon. "Both natural and social sciences", to quote the report, "are concerned with qualitative as well as quantitative methods. . . . Both employ deduction, classification and induction and take no account of values", except in so far, presumably, as the origin of values is a proper topic of scientific interest. The similarity of method is indeed becoming more evident now that both natural and social sciences are making wider use of statistical techniques. Economists are becoming less content to rely on deduction from self-evident axioms. They summarize factual data into index-numbers and 'multipliers', and are applying precise measurement to the national income. Occasionally even political scientists indulge in realistic surveys such as casting the proportion of public school men in British Cabinets. Social psychology in its studies of vocational selection, industrial fatigue and the like has always employed statistical methods, and social biology and demographic studies such as the measurement of the localization and structure of the industrial population are statistical in very essence.

Though the subject-matter of the social and natural sciences is different, there are many lines of research on the border of the two, in the pursuit of which workers both sides the border should co-operate. Social medicine, dignified by the recent creation of chairs at the Universities of Oxford and Birmingham, is a case in point; and the translation of new engineering techniques into the plans and planning organization of a factory should be another borderline study linked to the demographic problem of industrial location. A third borderline picked out by the Committee is that of social biology and social psychology. These deal with (1) the genetic basis of human behaviour, the influence of the quantity and quality of the population on social structure, and the converse influence of the social structure on the quantity and quality of the population; (2) the needs and wants of man, his preferences and aversions, motivation and educability in various types of social organization, the distribution of abilities and problems of recruitment.

The new emphasis on training of teachers for school biology with a view to national health, sponsored by the Central Council for Health Education and other official or semi-official bodies, points to another direction in which our universities will have to make provision for closer contact between naturalistic studies and social statistics.

The post-war problems discussed by officially appointed committees have been grouped into the physical lay-out of homes and of industry; and social security, either by providing the conditions for work and health or, at second best, compensation for unemployment and disability. All these problems, against which the Government is presumably making plans, require research for their successful handling and, in particular, co-ordinated research among the natural and social sciences. An efficient physical lay-out involves knowledge of geology, geography and engineering as well as the economic characteristics of industry. A successful plan for social security calls for knowledge of food values, vital statistics and the possibilities and limitations of the political and administrative set-up; and both a successful home and a successful security policy involves a knowledge of people's habits and ways of thinking that is by no means given to the individual sociologist and psychologist without systematic and objective research among the masses.

Clearly the interrelation of the natural and social sciences and their application to public policy are a two-way traffic. Greater knowledge of natural phenomena makes its impact on social organization; but the needs, wants and abilities of man require that human institutions make—in reverse—their own impact felt. It is a commonplace that new applications of natural science without appropriat social controls have led to mass unemployment monotonous labour, derelict industrial areas an concentration of economic power detrimental t community values.

What, then, are the practical measures that shoul be taken to implement the social research that i required as a basis of public policy ?

First and foremost, more importance should b attached to the social sciences in the form of endowment of certain branches of social research. It i sometimes thought that social research can be carrie on cheaply because little is required in the way o apparatus and laboratories. This is a profoun mistake. The major expense even in the natura sciences is made up of salaries for research personnel and the social sciences, if they are to base conclusion on a sufficient field of objective observation, statistically measured, will certainly need a large skille staff. Natural scientists are justifiably contemptuou of the armchair type of thinking by social scientists But if the sociologist is to leave his armchair for th field he must have trained armies at his command He cannot, in the complex situation that social lif presents, rely on a few select observations. H cannot reduce expenses by controlled experimen under laboratory conditions. So far from bein cheaper, effective social research is likely to prov more expensive than research in the natural science There is, of course, some justification for th economist who complains of the uninspired collectio of facts of trivial importance without guiding hyp thesis. Much expense can be saved by armchai thought, and co-ordination of working hypothesi with statistical fieldwork is a prime necessity. Bu however happy the marriage of theory and statistic the family budget is likely to run high.

Next to endowment, research on human institution needs, it is clear, close co-ordination.

It is mainly for this purpose that the Britis Association Committee proposes the setting up of Council for the Social Sciences. This Council woul co-ordinate the direction of research and the disbursement of funds, would initiate and supervis practical training and advise the Government on th preparation of official statistics in a fruitful form For it is on data collected by the Government tha factual social research must often rely; and all to often such research is frustrated by ill-conceived c inconsistent classification and tabulation. If an when the necessary expenditure is forthcoming, suc a Council might well carry with it the responsibilit for planning co-ordinated inquiries of social importance within the framework of a university development council.

Finally, social research needs the means fo publicity if it is to be brought democratically to bea on public policy. For this purpose, the Committe proposes the formation of a society for factual socia research in addition to the co-ordinating Counci Such a society would be formed on the lines of learne societies in the natural sciences, thus again illustratin the importance of mutual help and advice betwee the sciences, social and natural.

FUNCTIONAL COLLABORATION IN WORLD AFFAIRS

THE survey of the activities of the Middle East Supply Centre which appears in the centenary mber of the *Economist* is a valuable contribution the discussions at present centring on the value functionalism as a factor in promoting inter- tional collaboration. The success which has tended concentration on particular problems and e ease with which co-operation has been secured r some specific purpose, as the Hot Springs Con- rence showed, have suggested that functional -operation may be a means of persuading the wers ultimately to make the wide sacrifices in tional sovereignty which the preservation of peace ll demand. The Middle East Supply Centre is a ece of functional international machinery which s been evolved empirically and could be main- ined in its own area after the War. It serves a tural regional grouping, which is overwhelmingly ab, the industrial development of which has arcely begun. The States are fiercely nationalist d the very fact that the Middle East is a microcosm akes its experience of value as a model for similar ntres elsewhere.

While the war-time work of the Centre is chiefly regulate the flow of supplies into the area in the terests of war economy, it needs little imagination see the vital purpose which this simple piece of nglo-American organization could serve after the ar. Its staff is predominantly technical, scientific d young. Their chief work is to serve as a centre information and contact, to advise, instruct and ncourage the local authorities and to be, as it were, e guiding intelligence for the whole area. Already this way the Centre has been a general trans- tter of agricultural projects and improvements, cilitating the passage of successful experiments in ricultural development from one area to another. r example, it was only after the establishment of e Supply Centre that the excellent system of aling with the menace of the goat to afforestation Cyprus was brought to the notice of the Syrians, d successful experiments in growing seed potatoes ve been extended from Malta and Palestine to her Middle East States.

This pooling and exchange of information is sup- rted by surveys carried out by experts from the ntre into local conditions of agricultural production, th comments on how they could be improved. The ntre has also arranged for the provision of agri- ltural machinery, and important schemes of igation have been sponsored. Three of these are ing operated in Persia, another is under discussion r the headwaters of the Euphrates, while in Syria scheme which had been considered for years was rried through by the 61st Tunnelling Company of e South African Army at the request of the Middle st Supply Centre. Locust control is another ample of international action planned through the ntre. Research has established the fact that these vastating insects execute a regular nomadic cycle rough the Middle East, wintering in Southern Persia, to return through Iraq, Syria and Egypt to Abyssinia. No one Government could ever have dealt with this vicious circle, but the Middle East Supply Centre has been able to bring all the interested States together and achieve the essential co-ordination. Under the direction of Dr. B. P. Uvarov in London and with the assistance of the R.A.F. and the Red Air Force, exterminating crusades, operating from the air and on land the length of the Red Sea and up through Persia and Iraq, hold promise that for the first time in history the plague may be brought under control.

Medical services provide another example, and here the experience of the International Health Organisation of the League of Nations had already pointed the way. Apart from the standardization of drugs and equipment, the Middle East Supply Centre has resulted in official medical services coming in contact, in the R.A.M.C. and the American services, with some of the finest medical minds of Britain and the United States. The standard of public health has already been raised in this way, but scourges such as malaria offer opportunities for far more to be done.

These examples and others such as the creation of new industries or the assistance given to transport can scarcely fail to suggest to the scientific worker the value of the Centre after the War as a pool for all kinds of economic, social and technical services. In an area starved of technical efficiency, expert assistance would be always available without onerous political or economic conditions attached to its use, although the Governments concerned should be expected to contribute something in return for the advice they receive. Beyond this, the Centre would also be a planning headquarters. Its experts would conduct regular surveys of areas or problems and advise the Governments on the best methods of solving their difficulties. Any problem which was beyond the competence of the local authorities or involved two or more Governments could be referred to the Centre for expert opinion. It needs little imagination to realize the immense contribution which the Centre could make in such ways through energy, guidance and clear thinking. Irrigation schemes, roads, power, artesian wells, industrial development, all crossing and recrossing national frontiers, could, as the *Economist* truly observes, give a unity to the Middle East which five generations of pan-Arabism could not achieve, if indeed it did not provide the kernel of effective political unity.

The significance of a Centre of this type, beginning as a piece of effective machinery for regional planning, co-operation and research, and stretching out to regional health services, transport authorities, public utilities, industrial and agricultural development boards, is not confined to its adoption, more or less modified, as a model for other centres and as a stimulus to functionalism. It has a profound bearing on the whole development of colonial policy and planning. The article in the *Economist* rightly stresses the opportunity which this functional approach to the problem of pooling sovereignty offers to Britain, and the need for her to concentrate not on the export of business men and traders but on experts, technicians, medical men and scientific workers, who combine her great and humane traditions with the scientific and technical skill the twentieth century requires. The point was indeed made by Flexner in his discussion of English universities, when he emphasized the need of the British Commonwealth for trained men of wide disinterested cultural and scientific training, who could conduct organized attacks on the problems, practical and philosophical, of modern life. In that way might well come the creation of new markets, through the raising of standards of living everywhere, and the transition in Britain to a new industrial system based on high-grade products and services. But if colonial problems are no longer to be a stumbling block in international relations, if the question of access to raw materials is not to become academic, if commonwealth and empire are to be synonymous terms, colonial policy must take full account of these functional developments and turn them to the most effective use.

Much the same idea of functional development permeates the plea for imperial development on a much larger scale which is the essence of H. W. Foster and E. V. Bacon's "Wealth for Welfare". In urging the establishment of an imperial development authority which might be a prelude to an international authority, and would be organized on the lines of the public utility corporation, the emphasis is placed on the need for a factual approach, for continuity of policy and for adequate financial support. Whether in dealing with the economic development of a particular area such as British Honduras, which they use to illustrate their argument, or in describing the broad and more general work which might be entrusted to the proposed development authority, Messrs. Foster and Bacon stress the need for adequate research and experiment as a first stage. This must be the prelude to any extensive planning, and their suggestion that an exploratory research and development company should be formed first to acquire the knowledge and experience on which the organization of a permanent development authority could later be based, is characteristic of their outlook.

This scientific approach affords a sound basis for the conviction of Messrs. Foster and Bacon that economic development of the British Colonial Empire on lines primarily designed to promote welfare, and with resources and a long-term policy which will permit the cumulative benefit of the measures initiated to be reaped, is sound financially. What is striking is the extent to which their policy is already reflected in action. An article in the current number of the *Round Table* shows how the Hot Springs Conference has made an important addition to the technique of diplomacy and strengthened the collaboration of the United Nations. In a field where political action is also required to secure the solution of a technical or economic problem, it has done much to clear the way—so much that we might well encourage the idea of technical conferences as opposed to conferences of plenipotentiaries for clearing some of the ground in post-war problems.

Again, it is probable that the food organization is likely to serve as a source of technical and scientif advice to any commodity council set up by the Unite Nations as a political body to take executive actior and to secure a position of authority as an imparti source of information and advice in agricultural ar nutritional matters may well be the most importa part the food organization could play. By pr viding a meeting-ground for the expert and a foru for the discussion of matters of common concer and by conducting expert inquiries or undertakin at the request of governments or groups of gover ments, such a body would be invaluable in furtheri the aims of the Hot Springs Conference, irrespecti of the progress which may be made in organizi economic relations internationally in more gener fields.

The three notes struck in "Wealth for Welfar are equally clearly reflected in Colonel Oliver Stanley recent statements and speeches and in Governme action. In regard to research, for example, t Colonial Economic Advisory Committee recent established under the chairmanship of the Duke Devonshire to advise the Secretary of State matters of economic policy in relation to the Coloni dependencies, particularly matters of general poli arising out of programmes of economic developmen follows naturally on the Colonial Research Committ appointed last year under Lord Hailey as chairma It should also be remembered that Nuffield Colle is at present engaged on a three and a half ye scheme for research into economic and constitution questions in British tropical Africa. A Committee Colonial Studies set up to co-ordinate and advan these studies and an Institute of Colonial Studi financed by Nuffield College, are among four furth steps recently taken by the University of Oxford develop Colonial studies. Again, the importance comparative studies of labour problems as a field research is well brought out by Dr. Margaret Reid a paper, "Migrant Labour in Africa and its Effec on Tribal Life", in the *International Labour Revi* (**45**, No. 6 ; 1942) which has recently been reprinte Dr. Reid's preliminary survey shows how labo demands of an alien economic enterprise have co pletely undermined the old economic life of Nyas land and threaten its social life as well.

Colonel Stanley has explicitly recognized t importance of a factual basis for broad lines economic policy, and he has emphasized in a spee in the House of Commons on July 13 and also el where the necessity for liberal expenditure on colon development ; like Messrs. Foster and Bacon, appears to be convinced of the value and importan of such expenditure on an adequate scale. He rec nizes to the full the opportunity which the Colon Development and Welfare Act offers, and his wor on this point are the more important because insists that economic development must be link with educational advance, and that the two toget form the twin pillars upon which any sound scheme political responsibility must be based. This wo appear to be the only way of combining the sta of trustee with that of partner.

Colonel Stanley rightly pointed out that the spre of elementary education in the Colonies is a necessity for every social improvement; every economic development in some measure demands an increase of knowledge among the people. New health measures, the improvement of agricultural methods, new co-operative machinery for production and distribution, and the establishment of secondary industries, make demands on the Colonial peoples for co-operation to which they can only respond when they have educational opportunities. The Commission of Inquiry into higher education in British West Africa under Mr. Walter Elliot, Mr. Justice Asquith's Commission of Inquiry into the whole question of university training in the Colonies, and the course for training in leadership of co-operative societies at the London School of Economics, are the natural concomitants if the expenditure of large sums from the Colonial Development and Welfare Fund contemplated by the Colonial Secretary is to bear full fruit.

On the question of regional developments, Colonel Stanley was as explicit as on this functional approach. While he recognizes that the detailed planning must be done on the spot, he stated that the experience already gained by the Anglo-United States Caribbean Commission has led the Government to contemplate nore permanent machinery in which all the common oroblems of an area could be discussed. The Government would welcome the establishment of such machinery as the establishment of commissions for regions comprising not only the States with colonial erritories in the region but also other States which iave a major strategic or economic interest in the egion. While each State would remain responsible or the administration of its own territory, such a ommission would provide effective and permanent machinery for consultation and collaboration in promoting the well-being of the colonial territories, nd with this work the people of the colonial terri-ories in the region should be associated.

Colonel Stanley has thus associated himself with n idea to which General Smuts and Lord Hailey ave given some prominence, and in the debate in the House of Commons Sir Edward Grigg stressed the pportunity in such international collaboration of ssociating the self-governing Dominions with the dministration of the British Colonies. Even though the full responsibility of the tutelary Power of actual dministration of a particular territory is unimpaired, there are clearly difficulties in regard to such roupings, as the slightest review of any possible roupings in Africa, for example, will show. None the less, the experience of the Middle East Supply entre as well as that of Anglo-United States o-operation in the Caribbean has already indicated ossibilities which must be explored. If we keep entral direction to the planning of the broad schemes, ensuring continued, long-range planning and the provision of adequate resources, both in finance and n personnel, and entrust the elaboration and execu-on of detailed schemes to the local administration, e may best ensure the co-operation and interest of the individual communities and their leaders. At ast it is clear that the co-operative attack on articular problems and the planning of resources to that end, independent of artificial political boundaries, may prove an indispensable step in the mobilization not merely of our scientific resources for the wise development of these untapped sources of agricultural or mineral wealth, but also in securing that widespread human interest and understanding without which no plans for the attack on disease, on ignorance, on malnutrition or on poverty can be pushed to a successful conclusion.

TWO GREAT ARCHÆOLOGISTS

Time and Chance

The Story of Arthur Evans and his Forebears. By Joan Evans. Pp. xi+410+15 plates. (London, New York and Toronto: Longmans, Green & Co., Ltd., 1943.) 21*s.* net.

THIS is rather the saga of a family than a biography of an individual. Out of a genealogical welter (considerately illuminated by two family trees on the end-papers) of Evanses, Dickinsons, Grovers, de Brissacs, and several other families, there emerges first the Rev. Arthur Benoni Evans, a somewhat ineffective schoolmaster with artistic tastes, and an incipient collector of coins; then John Evans, who combined great efficiency in his Uncle Dickinson's paper-making business with first-class pioneer work in palæolithic archæology and in numismatics; and thirdly, Arthur Evans, whose career as an amateur insurgent in Dalmatia and an omnivorous collector in many fields culminated in a blaze of glory as the discoverer of the ancient civilization of Minoan Crete. Along with these there are sketches of Anne (Dickinson), the capable wife who saved Arthur Benoni's ramshackle career from disaster; of John Evans' three wives, and his brother Sebastian, "impecunious, versatile, and happy", who took after his father in lack of practical effectiveness but achieved some reputation by his translation of the "High History of the Holy Grail"; and of Arthur's brother, Lewis, whose fine collection of mathematical instruments adorns the Old Ashmolean building at Oxford. All these characters are admirably handled by Miss Evans, with a lightness of touch and a flavour of humour which commend and set off her mastery of her material.

The two outstanding figures, however, are, of course, John and Arthur, father and son, alike in their taste for antiquities, and in a flair in collecting which amounted almost to genius, but unlike in temperament and career. John worked hard in his somewhat unsympathetic uncle's business, earned wealth, position, and a high reputation as a forceful member of countless committees and councils; and, as a sideshow, took a leading part in the earliest discoveries of palæolithic man, was a first-rate numismatist, became president of the Society of Antiquaries, the Numismatic Society, and the Geological Society, vice-president of the Royal Society, and a trustee of the British Museum, and filled his house with collections of all sorts of beautiful and interesting objects.

Arthur was far less a man of business, was something of a rolling stone and strongly individualist, but equally a born collector and an archæologist gifted with singular insight and initiative. After a fairly successful career at Harrow, where he got prizes for Greek epigrams, English essay, and English verse, but made few friends, and a first class in history at

Brasenose, which failed to lead to a fellowship, he started in 1871 to explore Europe. He was financed by his father, and at no time troubled himself much about earning money, though he was glad to make something by contributions to the *Manchester Guardian*. From the first his affections were won by Dalmatia. He set his heart on Ragusa as a residence, visited the Balkans every year, and when in 1878 he married Margaret, daughter of E. A. Freeman, he almost immediately took her out there. Since 1875 he had been up to the eyes in Balkan politics, then exceptionally (even for them) perturbed. He was actively engaged in fomenting insurrections against Turks and Austrians, and writing fervid letters to the Press to denounce the oppressors. This was in the long run too much even for the comparatively easy-going Austrians (if the Prussians had been administering Herzegovina, it would probably have led to a firing party), and it ended in seven weeks' imprisonment at Ragusa in March–April, 1882, and a decree of expulsion from Austria. (It was currently reported in Oxford at the time that he was liable to be shot at sight if he set foot in the country again.)

Evans did not enjoy imprisonment, and thenceforth (apart from a somewhat farcical episode in 1909, when for a few months he was a Liberal candidate for the representation of the University in Parliament) he turned from politics to archæology. He pitched his tent in Oxford, and in 1884, by good fortune, the keepership of the Ashmolean fell vacant, and he was elected to it. Here was an opportunity, and Evans was the man for it. Archæology to him meant a great deal more than classical Greek art. The Ashmolean needed overhauling from top to toe ; he saw his way to making it a first-class museum of archæology, and (not without friction and combat and some hard words) he made it so. The new Ashmolean, now one of the first archæological museums in Great Britain, is very largely Evans' work.

But Oxford was not wholly congenial to him ; and a greater opportunity awaited him. Miss Evans makes a good deal of play with the phrase, 'Time and Chance' ; but in truth 'the Hour and the Man' would be more appropriate. So it had been with the Ashmolean ; but in 1897 the hour was that of the liberation of Crete from Turkish control, and the consequent possibility of excavation there ; and the man was Evans. For some years he had had his eye on Crete. He divined that there was something to be found there ; and he found more than he divined. He went to find writings in an unknown script, of which he had seen specimens on some seals ; and he found a kingdom, the kingdom of Minos, the predecessor of Mycenae, and the earliest phase of Hellenic or proto-Hellenic culture.

This is not the place to retell the story of the excavation of Knossos. In 1908 Evans inherited the properties of his father and his cousin, Tom Dickinson, and thenceforth he was a wealthy man, and able to carry out his work in his own way. What he made of it is to be seen at Knossos (if it escapes the hands of the vandals), and is recorded in the seven sumptuous volumes of "The Palace of Minos". Not until 1935 did he finally leave Crete, to pass the final years of his life at the house he had built on Boars Hill. Here, in 1941, his ninetieth birthday was celebrated by a deputation from the Hellenic Society ; and here, three days later, he died, full of years, riches, and honour.

Miss Evans is to be thanked and congratulated for the manner in which she has told the story of th
family, of which she is herself not the least distin
guished member.

F. G. KENYON.

MICRO-ORGANISMS IN EVERYDAY LIFE

Microbiology and Man

Being an Account of the Diverse Properties an
Characteristics of Micro-organisms, a Description o
the Various Tools and Techniques for their Handling
and an Inquiry into their Subtle Relationships t
Everyday Life. By Prof. Jorgen Birkeland. P
x+478. (Baltimore, Md. : Williams and Wilkins Co.
London : Baillière, Tindall and Cox, 1942.) 22*s*.

THIS book covers a very wide field, and appear
to have been written with the definite purpos
of attempting to serve as a basis for an understandin
of the part played by micro-organisms in everyda
life. It is divided into sections dealing with th
fundamentals of microbiology, infection and resis
ance, common infectious diseases and the micr
biology of food, milk, water, sewage and soils. Whil
it is too technical even for the instructed layman an
too diffuse for the student of specialized disciplin
in this extensive field, it is, nevertheless, a mos
readable and informative book, which should serve t
stimulate the student's interest and perhaps help hi
to decide the trend of his future studies. If the boo
falls into the hands of the non-technical reader th
extensive glossary of terms employed will be foun
extremely helpful ; but his subsequent readin
would have been much assisted if even a sho
bibliography had been appended.

There are some notable omissions from the text. I
the discussion on cholera, for example, there is n
mention of the serological grouping of vibrio
including the "El Tor" vibrios, differentiating th
Inaba type from related strains ; the serologic
classification of the Flexner dysentery group
passed over in silence, and in the reference to th
Weil-Felix phenomenon no account is given of th
part played by the 'Kingsbury' strain of *Prote*
(*Proteus XK*) in the serological diagnosis of mit
borne typhus (Tsutsugamushi and scrub typhu
The statement that all members of the genus Coryn
bacterium are parasites and are found closely ass
ciated with the skin of man or animals cannot pa
without comment. Not only are several speci
implicated in phytopathogenic conditions (for e
ample, *C. michaganense*, the cause of bacteri
cancer of tomatoes), but the researches of H.
Jensen have shown corynebacteria also exist as s
saprophytes.

Following the lead of Bergey's "Manual", t
author places *Salmonella sanguinarum* in the gen
"Shigella", although it is serologically identical wit
and culturally similar to, *Salmonella pullorum*, and
included in the genus Salmonella by the Salmone
Sub-committee of the Nomenclature Committee
the International Association of Microbiologists.

It is unfortunate that there are many printe
errors in the text. To cite a few examples, *Bruce*
abortis is given for *Brucella abortus*, *Pasteure*
tularense for *Pasteurella tularensis*, *Streptococ*
scarlatina for *Streptococcus scarlatinæ*, and *Salmone*
abortus avi for *Salmonella abortus ovis* ; also in t
names of authorities, Ogston, Kitasato, Muckenf
and Vasco da Gama are misspelled. The discove

of the causal organism of Malta fever (*Brucella meli- ensis*) is said to be Sir Robert Bruce and not Sir David. Here is a possible confusion with Robert the Bruce, whose field work, so tradition relates, was oncerned with fundamental studies on the habits of the Arachnidæ and not with micro-organisms!

Some of the historical notes are most entertaining and do much to enliven the pages of Prof. Birkeland's olume. One feels, however, that the author is appiest in the concluding chapters of his book, ealing with microbiology of food, milk, water, ewage and soils. The chapters on microbiology and ater and on sewage reach a high standard of clarity and excellence.

R. ST. JOHN-BROOKS.

ENGINE RESEARCH

he Chemical Background for Engine Research

dited by R. E. Burk and Oliver Grummitt. rontiers in Chemistry, Vol. 2, published under the spices of Western Reserve University.) Pp. xii+ 97. (New York: Interscience Publishers, Inc.; ondon: Imperia Book Co., Ltd., 1943.)

N recent years increasing attention has been paid to ways and means of keeping students and dustrial scientific workers abreast of advances in ose branches of fundamental research which have application to their work; and facilities are now ailable which, although still imperfect, have gone long way to meet the requirement. The publication classified abstracts, for example, is an essential rvice to this end, the value of which is unquestioned. addition, the compilation of progress reports and ecial monographs affords a means of supplementing e abstracts by periodic critical reviews of con- mporary work. It is thus possible, in most in- ances, to obtain a reasonably comprehensive count of the present state of knowledge in any rticular branch of science without a laborious arch through the literature.

The volume under review represents a contribution the latter category of publications. It originates a project sponsored by Western Reserve University bringing graduates into personal touch with ups of distinguished workers in selected fields, to ar first-hand of the researches in progress and of directions in which significant advances are being de. The lectures given by the various groups are erwards published in a series entitled "Frontiers Chemistry". Two volumes have appeared so far itled, respectively, "The Chemistry of Large lecules" and "The Chemical Background of Engine search".

The six contributors to the latter volume, E. F. ck, F. D. Rossini, F. C. Whitmore, G. von Elbe, Lewis and O. Beeck, are well known in Great tain for their pioneer work on the physical and mical properties of hydrocarbon fuels generally l on the internal combustion engine, and their sidered views on engine research therefore con- ute an important contribution to the literature of subject. The scope of the lectures is compre- sive, and includes methods of synthesis of complex rocarbons, a clear summary of their combustion racteristics, recent theories of combustion, chemi- thermodynamics of hydrocarbons and physico- mical aspects of lubrication. To the student of bustion the lectures by Fiock, von Elbe and Lewis are of particular interest in that they assemble all the relevant experimental data relating to the oxidation of hydrogen and the simpler hydrocarbons and proceed to show how the observed phenomena may be fitted into a general theory of combustion. The result is not entirely satisfactory. Indeed, Fiock, in his second lecture, states ". . . it may truthfully be said that not a great deal is actually known of the highly complex mechanism by which the chemical energy latent in the combustible mixture is transformed into usable mechanical energy"; and the reader will probably come to the same conclusion.

The shortcomings of the theory, outlined in von Elbe's contribution, arise partly from the fact that in no single instance have the combustion characteristics of a hydrocarbon been determined experimentally over the full range of reacting mixtures, and partly owing to a tendency to cling to the simple mechanical analogy which came into vogue in the early days of the atomic and kinetic theories.

In considering any mechanisms for combustion, it is necessary to distinguish clearly between ascertained fact and surmise. Experiment in general only gives information as to the identity of stabilized products which survive when a reacting medium is suddenly chilled; it gives no accurate data as to the instantaneous composition of the medium at any stage of the combustion. In consequence, kinetic data based upon chemical analysis or observations of changes in pressure are difficult to interpret save in the case of slow reactions between simple molecules. There is, however, strong evidence that combustion processes involve, in many instances, an orderly interchange of energy of a specific kind represented in the mechanical analogy by the links of chains, either single or branched; and to account for the kinetic data it is now customary to identify the chains with the formation of free radicals by the initial dissociation of the reacting molecules, and their subsequent interaction with other radicals, atoms or molecules in a series of elementary chemical reactions.

As to the composition or even the existence of free radicals in such circumstances, experiment tells us little. Indeed, von Elbe points out that in the case of any particular hydrocarbon "the reactions considered to be of consequence are selected because by means of the kinetic theory of gas reactions they yield equations which, after introducing certain numerical values, correctly describe the dependence of explosion limits and reaction rates on the experimental variables pressure, temperature, vessel diameter, mixture composition, and nature of the surface; and because no alternative, or at least no plausible alternative schemes yield the correct relation. There is no method known by which the individual chain-carrier reactions may be studied independent of each other".

It will be clear from the above that much exploratory work of a fundamental character yet remains to be done before a generally acceptable theory of combustion can be formulated.

In conclusion, it may be well to remove the impression that the lectures deal solely with the more recondite aspects of combustion theory. They have, in fact, a strong practical trend, and give adequate emphasis to experimental methods and to such important factors as engine 'knock' and lubrication. The book is well illustrated, and useful bibliographies are given by each contributor.

D. M. NEWITT.

OPTICAL TOPICS IN PART CONNECTED WITH CHARLES PARSONS*

By The Right Hon. Lord RAYLEIGH, F.R.S.

The Parsons Family, and Parabolic Mirrors

PARSONS belonged to a type peculiarly British. We have been called a nation of amateurs, and probably most Englishmen when they repeat the phrase do so not altogether without complacency. So far as the saying has any definite meaning, I think that Parsons' character and methods of thought go to exemplify it. This may seem to some a paradox, and no doubt the building of a twenty thousand kilowatt turbo-alternator, together with the accompanying technique of drawing office, patent specification, licences to outside manufacturers, and so on, seem very far from the amateur workshop and its atmosphere. But these huge machines, on which the industrial prosperity of whole districts may depend, had their prototypes in the constructions of wire, paper, cardboard and sealing wax, which could be seen on the mantelpiece of Parsons' study in Mayfair. What I want to convey is that though Parsons was thoroughly informed as to the conventional procedures of engineering, he had no superstitious reverence for them, and was if anything biased in favour of doing something different, if there was even a possibility that it might be an improvement.

The Hon. Sir Charles Parsons, O.M., K.C.B., F.R.S.

Parsons' father, the third Earl of Rosse (1800–67), was, like his son, a man of mechanical genius, and it is a matter of interest to trace the relation between the careers of the two men. The portrait of the father, in the rooms of the Royal Society, is strongly reminiscent of the son as I knew him. The aspect is mild and beneficent: and in Charles Parsons' case strangers who, without knowing their man, presumed unduly upon it, were apt to receive a rude awakening.

Lord Rosse's great telescope of 6-ft. aperture was built with only amateur resources and the assistance of estate carpenters and workmen from the local rustic population taught by himself. The records of his work in telescope construction were collected and reprinted by his son[1], and it is easy to see in this volume the hereditary source of Charles Parsons' mechanical genius. The spirit and mentality of the son's work are closely traceable in that of the father. Lord Rosse's great telescope was notable in the history of astronomy for the discovery of the spiral structure of the extra-galactic nebulæ; and, as we can now see, there were not a great many other problems for which it would have been suitable. The great modern reflectors owe their usefulness to their accurate driving clocks, and to the mode sensitive plate. In Lord Rosse's day, these thin were still in the womb of the future. I rememb discussing his father's work with Parsons, and expressed the opinion that, given his financi resources, and given the contemporary state development of the mechanical arts, it would scarce have been possible for him to do more. He told that the sum expended was of the order of £10,00 This, of course, brought no financial return, nor c it have been expected to do so, in spite of the fa that the elder Herschel had made a living by t sale of the reflecting telescopes which he constructe

Judged by the precedents of those days, and by t then value of money, £10,000 was no doubt a ve large sum to spend on astronomical equipment, a possibly some contemporary critics may have thoug that the discovery of the spiral structure of t nebulæ was an inadequate return for it. If, howev we recall that this discovery was a fundamental o for the general structure the universe which, broad speaking, is believed to co sist entirely of such nebu to the number of perha 10^{10}, we may see things in truer proportion. It may a be illuminating to think of t cost even of a minor warsh of to-day, and to compare with the cost of Lord Ross telescope.

Some have perhaps gain the impression that Lo Rosse's interest was more the construction of the te scope than in the use of It may be admitted that one who had not been carr on by keen interest in mechanical processes wo have been able to get throu such a task. On the ot hand, it would be wrong suppose that the possibilit of the completed instrum were not adequately made of. Lord Rosse tells us th for a period of seven years after the construction the telescope, few favourable opportunities observing with it were lost. The conditions of were very unlike those of a modern instrument; it was only maintained fit for use by periodically polishing the speculum metal mirror, which requi a skill comparable with that of the original figuri

It is not perhaps over-fanciful to suggest t Lord Rosse's telescope bore the same kind of relat to the great telescopes of to-day that the three-dec of his day bore to the modern ocean steamship. each case the machine was effective for its purp and could do wonderful things in skilled ha Ropes, chains, pulley blocks, carpentry and bla smith's work took the place of precision engineer Far inferior mechanical resources were available the construction, and far more was demanded in way of personal skill and muscular effort from user. This is the rule of progress. No though person considers that the effort represented by obsolete machines was wasted, for they were ne sary steps on the road. The results obtained them gave the needed stimulus for fresh efforts b ater generation, and brought into view the problems which remained to be faced.

---

* Parsons Memorial Lecture delivered before the Physical Society on October 15.

The modern telescopes of to-day are among the highest developments of precision engineering. In Lord Rosse's day precision engineering as we know t scarcely existed; indeed, the word itself was of comparatively recent origin, those of the craft still being often called millwrights. Lord Rosse belonged o the transitional period when modern precision engineering was in the process of birth, and among his friends were some of the main contributors to it; for example, Charles Babbage (1790–1870), whose calculating machine, though never completed and representing much wasted intellectual effort, was the means of greatly raising the standards of precision in mechanical construction.

The records of Lord Rosse's work on telescope construction, some of which were not very accessible, were collected and reprinted by his son towards the end of the latter's life, and those who knew Charles Parsons can easily trace in the volume the hereditary ources of his mechanical genius. The same spirit and mentality pervades both. Neither of them had much literary gift, and their titanic achievements are described in a matter-of-fact style designed simply o tell what they have to tell without any desire to make a fine story of it. I recall many years ago that Charles Parsons, in giving me a copy of "The Evolution of the Parsons Steam Turbine", by Alexander Richardson[2], said, in a half-apologetic way, "It is rather a florid sort of a thing". Looking at the book again, I do not think it is, in fact, open to this criticism. All that can fairly be said is that Parsons' mechanical triumphs are described by Richardson in a style not quite so reserved as Parsons' own.

Charles Parsons can have had comparatively little opportunity of learning directly from his father, who died when he was only thirteen years of age. The astronomical and mechanical traditions of the family were carried over the intervening period by Charles Parsons' elder brother, the fourth Earl of Rosse 1840–1908), who, though not perhaps possessing quite the tenacity of purpose of his father or of his younger brother, had a considerable measure of the same kind of gifts. He was best known for his observations on the radiant heat of the moon.

Lord Rosse's great interest in the problems of optical construction was fully inherited by his younger son, Charles Algernon Parsons. The most practical fruit of these researches was in the manufacture of searchlight mirrors. He developed a method of making these which, from the scientific point of view, was an interesting new departure and which moreover proved a commercial success, though it has been overshadowed by his work in other fields.

The idea of using the electric arc for a searchlight goes back to days before the development of the dynamo machine, when a large number of Grove cells was the source of current; and there are indications in the literature that inventors were at work from that time on. The concave mirror necessary for hrowing out a parallel beam may be made of metal or of glass. Metal was used in some early projectors by Siemens, and it was readily shaped into a deep parabolic form by spinning or otherwise. The surface was gilded. Metal searchlight mirrors, though occasionally revived, are now almost obsolete, at any rate in Great Britain, owing to the inferiority of reflecting power, and the difficulty of maintaining it good under service conditions. In this respect, silver under glass is far superior, but to make a deep mirror of glass and of accurate parabolic form at a reasonable price was a matter of no small difficulty.

Convex and concave spherical mirrors of glass silvered at the back were no novelty. They were used as ornaments from a very early time. Thus, in Van Eyck's portrait of Jan Arnolfini and his wife in the National Gallery, painted in 1434, a convex mirror hanging from the wall reflects the contents of the room. Large mirrors of this kind became fashionable as ornamental furnishings towards the close of the eighteenth century. There is a fine example mounted as a convex mirror in the library of the Royal Institution. The diameter is 28 in., and it is 'silvered' with amalgam on the concave side. This mirror can be seen in the well-known engraving of a group of leading scientific men of the day gathered in the same room in the year 1807.

Such mirrors were and are given their preliminary shape by gradually heating up the glass disk, and allowing it to sink by gravity into a concave mould as soon as the glass becomes soft. They are then annealed and after cooling are ground and polished with spherical tools, in the same way as lenses are ground and polished.

Such spherical mirrors are, however, of very limited use for searchlight work. To get brightness it is necessary to take up from the arc a cone of light having a large angle and make it parallel. If we attempt to take up a cone of, say, 60° by extending a shallow spherical mirror of given radius so that it becomes deep, the additional light is not sent where we want it, but finds its way out laterally, away from the axis of the beam. This is the effect called spherical aberration, and it soon sets a limit to the useful angle of the cone of rays which can be collected by a spherical mirror. On the other hand, the optician, accustomed to produce accurate spherical surfaces of glass by the well-tried and effective method of abrading them with circular strokes on a spherical tool, is reluctant to abandon the spherical form. In 1874, Col. Mangin, of the French Engineers, devised an ingenious method of extending the usefulness of spherical surfaces. This amounts in effect to making the glass into a concave meniscus lens, and silvering the back surface. We may regard such an arrangement as a concave spherical mirror covered with a concave meniscus lens. Remembering that the parabolic form is the ideal, it is evident that the outer zones of a spherical mirror tend to converge the rays too much compared with the inner zones. The superposed zone of the concave lens tends to diverge the rays and with increasing effect in the outer zones. By a suitable choice of curvatures these effects can be made very nearly to compensate one another, provided that too deep a mirror is not aimed at. In this way the spherical aberration is corrected, while the constructional advantage of spherical surfaces are retained.

Such is the nature of Mangin's invention, which in its day was extensively used, and especially in France from about 1882 until 1921. Parsons is said to have regarded it with some favour, though I do not remember to have heard him on the subject. These mirrors were, however, expensive to make, and the necessary thick edges made them heavy and liable to crack with the heat of the arc. The principle did not admit of a very favourable ratio of aperture to focal length, and this ratio did not usually much exceed unity.

So far we have only considered spherical glass mirrors, and previous to 1886 no other glass searchlight mirror had been made. The mechanical problem of making a parabolic searchlight mirror of deep curvature has of course little in common with the problem of parabolizing a telescope mirror, which is of such shallow curvature that the parabolic form can be derived from the spherical by local polishing towards the middle.

Charles Parsons appears to have turned his attention to searchlight mirrors so early as 1886, when he was with the firm of Clarke, Chapman, Parsons & Co. He was probably led to do so by the family tradition of making reflecting telescopes, but it must be remembered that he was also concerned with the manufacture of electric lamps. He devised a method of making good parabolic mirrors of silvered glass at a cost which was not too great. This method had many points of novelty and was kept a close secret for years, only a few trusted employees in the Heaton Works and a few personal friends of Charles Parsons being privy to it. However, as in all such cases, it leaked out in the end, and after the War of 1914–18, when the demand for searchlight mirrors had for the time fallen to a very low ebb, it had become widely known, and Parsons told me that he no longer regarded it as a secret.

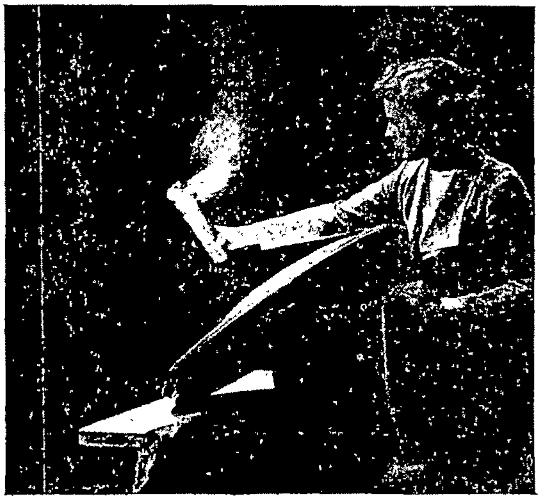
This method so far resembled the old traditional method of making convex and concave spherical mirrors already mentioned, that the flat glass was bent into a curved form by moulding from a flat disk at the lowest temperature which will make it plastic. I am inclined to think from the way Parsons spoke to me that he had re-invented this process and did not realize, any more than I did myself, that in its cruder form it was an old one. There is not much, if anything, to be found about it in print, either in its old or its newer form. Parsons' improvements consisted in using a disk of plate glass, already ground and polished to flat surfaces, and pressing it between cast iron moulds or formers, accurately turned to a paraboloidal surface. In a later improvement the concave former was alone used, and the softened glass was brought into close contact by applying a vacuum through a small hole in the metal. After annealing in a gas-heated oven, the surface was fine-ground and polished a second time. Since the surface was now paraboloidal, this could only be done by spherical grinding and polishing tools of small size. These tools could only be an approximate fit for the local curvature of the paraboloid, but the polisher, being of felt, had some power of adaptation to the surface on which it rested.

A process of this kind could not, of course, produce an absolutely certain result, and each finished mirror was tested optically with the help of a collimating lens, by determining the focal length of each separate zone, screened off from the remainder. This resulted in a certain percentage of rejections.

One of these mirrors in a wooden frame, which formerly hung on the staircase of Parsons' country house, Ray, near Kirkwhelpington, Northumberland, is now in my possession. It is of plate glass, $\frac{1}{4}$ in. thick. The diameter is 24 in. and the focal length $17\frac{1}{2}$ in. The depth of the concavity is more than 3 in.

Much larger mirrors than this one were made, up to 7 ft. in diameter. Even the 2-ft. mirror, taken out into the sunlight and used as a burning glass, will readily set a large log of green wood on fire.

About the same time that Parsons developed his method of making parabolic mirrors, the firm of Schuckert in Germany was attacking the same problem in a different, but in some respects a mor obvious, way. They, too, probably moulded th glass approximately to the desired shape. Thei subsequent process amounted in effect to turning th glass on a vertical lathe, the lathe tool being a smal rotatory grinder, and the motion transverse to th lathe axis being guided by mechanism which cause the small rotatory grinder to follow the desire parabolic path. There is little or no informatio available in Great Britain beyond the meagre account given in patent specifications, and only those wit practical experience of both could fully decide th relative merits of this process and the process o Parsons. The criterion of cheapness in the finishe product was very much in favour of the latter, an if I judge rightly it will probably appeal to mos engineers as the more mechanical method of the two In either way the parabolic form is attained b turning on a lathe, guided by suitable mechanism but while Parsons did this operation once for all o the metal former, Schuckert did it on the glass fo each individual mirror. So far as the results go, i appears that the necessary accuracy of figure can b attained by either method. This accuracy is, o course, of an altogether lower order than is necessar for telescope mirrors, where the figure must no depart from the paraboloid by more than a fractio of a wave-length at any place.



PARSONS' 2-FT. PARABOLOIDAL MIRROR USED AS A BURNING GLASS.

The Mangin mirrors, which were necessarily thic at the edges, were probably made by grinding ou the concavity, but they were very expensive.

To make a thin paraboloidal mirror of deep curvature out of a solid disk by grinding the material awa would be a barbarous proceeding; like whittlin away a large tree trunk in order to make the shaf of a spear, as the Australian aborigines are said t have done. Owing to the depth of curvature, th difference between the spherical and the paraboli form is too great to be attained by the tentativ methods used for parabolizing reflecting telescope If glass is to be used at all in place of metal, we ar practically limited to moulding it while soft, a Parsons did. It is not, perhaps, certain that he wa the first to produce an approximate parabolic for in this way. What he certainly did do was to carr out this moulding process with the greatest possib accuracy, and to use the parabolic form thus produce to guide the subsequent operation of fine grindin and polishing. This feature appears to have been entirely new. It was not patented, and he kept it secret as long as he could, probably judging that a more effective protection would be obtained in this way*.

During the later years of his life, Parsons became keenly interested in the production of large glass disks for reflecting and refracting telescopes. In the case of reflectors, he had a number of original ideas, and his mind was full of the subject right up to the day of his death.

As it seemed to me, he regarded Heaton Works, of which he was practically the sole owner, partly indeed as a money-making concern, but also largely as a source of personal pleasure, and a place where interesting and amusing large-scale experiments could be tried. The attitude was rather that of progressive landowners like Coke of Norfolk early in the nineteenth century towards their estates and farms. Parsons' successors, who had to consider their shareholders, could not carry on in this spirit and had to abandon experimental projects which were liable to fail, and which in any event did not hold out the hope of large profits. The result was that this epoch of bold experiments in the field of telescope-making at Heaton ended with Parsons' death, many projects of some promise having to be abandoned. One or two of them may be mentioned. Thus, in the case of reflecting telescopes, the problem was to make disks large enough for the projected 74-in. mirror for the University of Toronto and the 200-in. mirror for the Carnegie Institution. No definite orders had been received for these, but the chance of receiving the order naturally depended on the proof of ability to carry it out.

The largest glass mirror than existing was the 100-in. of the Mt. Wilson Observatory, which is 13 in. thick and was made from a disk supplied by the St. Gobain Plate Glass Company. This had only been produced with difficulty, and Parsons looked round for some easier method than that of casting the mirror at one operation. He reflected that there would be no difficulty in cutting disks of this diameter and of moderate thickness from commercial plate glass. Could not a number of such disks, carefully cleaned and placed in a pile, be fused together at a moderate heat ? We may recognize here a certain kinship to the general line of thought which had led to his method of making parabolic mirrors, again by the use of moderate heat. A number of trials were made on a comparatively small scale, and some of them were successful. Thus, for example, four circles of ¾-in. plate glass, 17 in. in diameter, were united into a single disk 3 in. thick, by heating to 650° C.

These experiments suggested another idea. A cellular glass disk is, of course, much lighter than a solid one, and is not necessarily much less rigid. The fusion method seemed to lend itself to this, and was tried with some success. In one experiment two circles of ⅜-in. plate glass 12 in. in diameter, separated by a layer 1¾ in. thick of granulated glass, were heated to 650° as before. The whole became welded into a coherent disk, which behaved satisfactorily. Larger experiments of the same kind were made, but without full success. It is not clear, however, that the limitations of the method (if any) were established.

In spite of these fairly encouraging results, Parsons seems ultimately to have preferred a rather different method. In one experiment he used three disks of optical flint glass 9½ in. in diameter by 1 in. thick, the adjoining faces having been previously ground flat and polished. This assembly was raised to fusing temperature and flowed out into a disk about 11½ in. in diameter and 2 in. thick. This appeared to be to all intents and purposes a solid disk. It seems that this experiment gave a satisfaction and confidence that the other experiments had not given. It was Parsons' intention to make the 76-in. disk for the Toronto reflector by this method, but owing to his death and its financial repercussions the work was not carried out, and the Toronto mirror was ultimately made of Pyrex glass by the Corning Glass Co. of New York. It was, however, ground and polished at Heaton.

Newton and the Dark Lines of the Solar Spectrum

I have tried to recall, as was fitting, something of the history and spirit of one part at least of Charles Parsons' activities*. I turn now to another optical topic which has no direct connexion with him, and which is scientific rather than practical. If he were still with us it would without doubt have found in him a sympathetic listener.

Telescopes and spectroscopes, as we ordinarily know them, depend upon the use of lenses, and as the subject is usually expounded, it might seem that lenses were of the essence of these instruments. My thesis will be that it is not so, and that a telescope or spectroscope of fair performance can be set up without the use of lenses. The foundation is in work done by my father before I was born. I hope to be able to add a few points to it.

In preparing an address for the recent Newton Tercentenary, the question presented itself: What minimum conditions are necessary for observation of the Fraunhofer lines in the solar spectrum, and how was it that Newton when he examined the solar spectrum in 1672 onwards failed to observe them ? It may seem that this should be a fairly simple question. Several eminent authorities have given their opinion upon it, but, as will be shown, they have not given a correct answer. This will lead on to the question of how far lenses are essential in the telescope or the spectroscope. It will be shown that a telescope can be constructed without lenses (or mirrors) which is fairly adequate for examining the degree of 'solar activity' as measured by the size and number of sunspots. It will be shown further that a suitably designed spectroscope with a single prism of ordinary flint glass and without lenses will show the Fraunhofer lines in the solar spectrum. Naturally, in discussing so well worn a theme as the simple spectroscope, one can only hope to say anything of novelty on a few points. On the other hand, the subject is not so specialized as to be overgrown with refinements which appeal only to the few.

---

* In a pamphlet entitled "The Theory of Searchlights" (anonymous) published by H.M. Stationery Office on behalf of the War Office in 1935, it is stated that

> "The first practical reflectors of paraboloid shape were made by Messrs. Chance who pressed the glass into shape without grinding the surface. These were inferior to the Mangin type."

This, if correct, would be the nearest approach to an anticipation of Parsons' invention. I communicated with Messrs. Chance, but their director of research, Dr. W. M. Hampton, who kindly looked into the matter, was unable to find any evidence that they had made parabolic mirrors in this way previous to 1935.

* I gave my personal recollections of him in a paper which was printed as an introduction to "Scientific Papers and Addresses of the Hon. Sir Charles A. Parsons", edited by the Hon. G. L. Parsons (Cambridge, 1934).

The first experiments on the spectrum which Newton described in the *Philosophical Transactions* in 1672 and afterwards in his "Optics" were made by passing a beam of sunlight which came from a small hole in the shutter through a prism placed close to the hole, the spectrum being received on the opposite wall. He regarded this arrangement as producing a series of images—what are now called 'pinhole' images—of the sun in the various colours, though he did not himself use this expression, and indeed the hole he used was one third of an inch in diameter. Subsequent writers of high authority, including Brewster, Helmholtz and Michelson, have implied with varying degrees of definiteness that Newton made no subsequent improvement on this arrangement, and one can only assume that they had got their information from second-hand accounts without studying the original.

Brewster, for example, says[3]: "Had Newton received upon his prism a beam of light transmitted through a very narrow aperture [instead of a round hole] he would have anticipated Wollaston and Fraunhofer in their fine discovery of the lines of the prismatic spectrum. In 1802, Dr. Wollaston, by transmitting the light of the sky through an aperture one-twentieth of an inch in width, discovered six fixed dark lines in the spectrum, one in the red, one in the orange, one in the blue and one in the violet".

Wollaston, however, did not project the spectrum, but observed it subjectively by holding the prism to his eye.

Helmholtz[4] says that Newton did not use the methods which are necessary to obtain a complete separation of the various rays, and therefore he too did not see the Fraunhofer lines in the sunlight. Michelson[5] also implies that Newton did not use the slit and the focusing lens.

All these distinguished authors, however, are mistaken upon the point. Newton says[6]: "In the sun's light, let into my darkened chamber through a small round hole in my Window-shut, by which the image of the hole might be distinctly cast upon a sheet of white paper. . . ." On p. 49: "Yet instead of the circular hole *F* it is better to substitute a long parallelogram with its length parallel to the prism *A B C*. For if this hole be an inch or two long, and but a tenth or twentieth part of an inch broad or narrower: the Light of the image will be as simple as before or simpler, and the image will become much broader" [that is, the spectrum lines will be longer].

Another explanation is given by Kayser[7]. He says that a spectrum 25 cm. long, with a slit width of 1 mm. as used by Newton, should easily show the Fraunhofer lines, and he puts down Newton's failure to observe them to the fact, incidentally mentioned by Newton himself, that his prisms were of bad quality glass. A prism said, apparently on good grounds, to be one of his still survives in the British Museum, Department of British and Medieval Antiquities*, and it would be of interest to try it, but it is not accessible at present.

In any event, we cannot fully explain the difficulty in this way. Newton describes how he made up a hollow prism with flat polished surfaces (mirror glass) and filled it sometimes with water, sometimes with an aqueous solution of "Saccharum saturnii" (lead acetate) to increase the refraction, or rather as we should say, the dispersion. I have personally been able to see the Fraunhofer lines without difficulty and at the first trial, using a water prism of 60° angle and ordinary size. The spectrum was projected upon a screen by a lens of about 10 ft. focus. All these explanations which have been given of why Newton failed to see them, fall to the ground, because without using means superior, or even equal to his, a modern observer can readily see them.

In trying to understand how this happened, we must remember that the advantage of knowing what to look for is not easily over-estimated. Seeing that the phenomenon itself observed in this way is not very spectacular, the explanation seems adequate. It is not intended to depreciate Newton's great experimental skill, which, if I may venture an opinion, was equal to that of any man of whom we have knowledge. It is perhaps conceivable, after all, that he did see the lines, but that not having any reason to suspect the great importance of the matter, did not feel moved to probe it further, and passed it over in his written accounts.

The Telescope and the Spectroscope without Lenses

The view sometimes expressed that Newton failed to see the dark lines of the spectrum because he did not use a lens to form an image of his aperture is erroneous, because, as we have seen, he *did* use a lens. Nevertheless, the interesting question is raised of how good an image can be obtained without a lens. We need not introduce the question of prismatic dispersion at this stage. Everyone knows that you can get an image with a pinhole, but (it is usually supposed) not a very good one. My father discussed the question of how good an image could in fact be got. We are between Scylla and Charybdis in this matter. If we make the pinhole too large, we may in imagination divide it up into several apertures in different positions. Each of these gives an image in a different position, and the superposition of these produces confusion. If we make the pinhole too small, then the image of any one point on the object is widened by diffraction, and overlaps the images of other points, so that again we have confusion. Evidently there must be an optimum size for the pinhole. What is that size ?

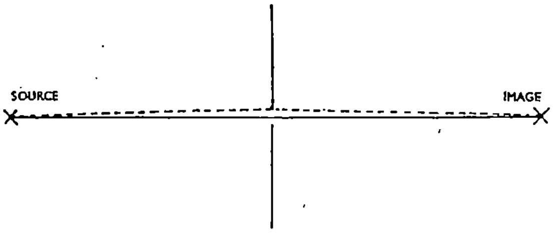
In order to see this, it is a good plan to go back to the consideration of a lens, focusing a small source on a screen. What the lens does is to make the optical length from the source to the image the same for every path. The geometrical distance is no longer for a marginal ray than for a central ray, for the former path is bent and the latter straight, but the retardation of the light by glass makes up for this, and when the lens is in position, the effective distance (optical length) is the same for both, and the light arrives at the focus in the same phase from every part of the aperture. That is the essential function of a focusing lens, and it is only in so far as it does this that the lens is effective.

Now clearly if the aperture is small enough, the light *will* arrive in the same phase at every part of the aperture even without a lens. The question is, How big can we make it without introducing an important difference of phase ?

"Important" is, of course, a vague phrase. There can be no doubt that complete opposition of phase would be important, and certainly we shall harm the

---

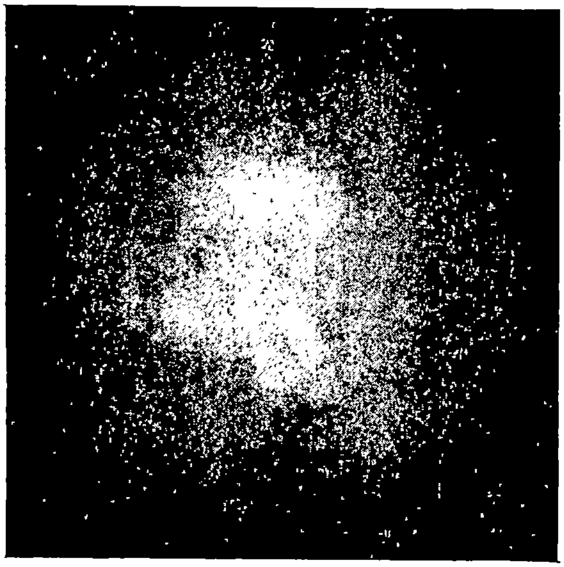
* See Rev. H. T. Inman, "Sir Isaac Newton and one of his Prisms". Privately printed (Oxford, 1927). I have not been able to consult this book and should be grateful to anyone who could give me the opportunity. It does not seem to be in any of the chief libraries. See also *British Museum Quarterly*, 2, 53 (1927–28).



definition if we introduce so large a difference of phase as this. On the other hand, we must not be too particular for the reasons already explained. We must allow a fraction, but only a fraction, of a period, and the fraction $\frac{1}{4}$ complies with this, and is justified by a closer consideration of the subject than can be attempted here.

If we want good resolving power, we must have large aperture, for the definition depends wholly on the aperture. The admissible size of aperture is determined by the consideration that the marginal ray is not to differ in phase from the central ray by more than a quarter of a period. This consideration alone does not fix the size of aperture, for supposing that we have set up the apparatus and find that the difference of phase is more than the specified amount of a quarter period, we can diminish it either by reducing the aperture, or alternatively by going farther off. If we go infinitely far away, no aperture of finite size is too great, so that in principle we could make as large a telescope as we like without an objective lens. However, if we attempt more than a very modest aperture, we shall find the necessary distance impracticable, for it increases as the square of the linear aperture. In my case, the distance available if the light was admitted at one end of the room was 19·6 metres ; taking λ as 5×10^{-5} cm. the admissible aperture $\sqrt{2 f \lambda}$ is 0·44 cm.

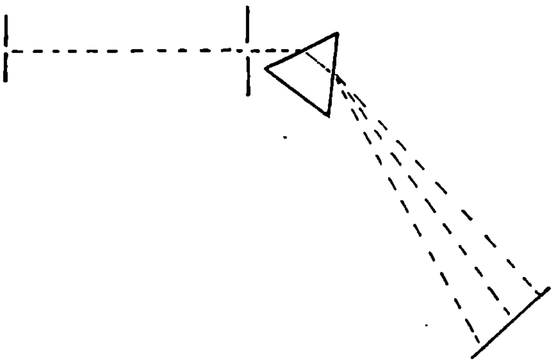
An iris diaphragm was placed in the window shutter, and could be adjusted to this aperture. The sun's light was reflected into the aperture and the image found of it was received on a sheet of paper 19·6 metres distant. When there were spots on the sun, they could usually be well seen on the paper. It is true that naked-eye sunspots do occur, though rarely. But ordinary small spots invisible to direct scrutiny, either with or without a dark glass, can readily be seen with the pinhole camera described. With the camera no dark glass is required*.



PINHOLE PHOTOGRAPH OF THE SUN SHOWING A SUNSPOT.

It may be objected that the 0·44 cm. as calculated is not much more than the aperture of the eye. This is no doubt true when the eye is dark adapted, and the iris fully open. But in these circumstances the eye by no means gives as good definition as the aperture would admit of. For the detection of sunspots at least, the pinhole camera is far superior to the unassisted eye. By going fairly close to the image, we can easily see it under a visual angle of, say, 20° or 30°, whereas the sun viewed directly subtends only $\frac{1}{2}°$, so that the magnifying power may be 40–60 diameters ; but, owing to the small aperture, this arrangement must not be expected to show the detail usually associated with that magnification. Magnification is, of course, no real criterion of what a telescope can do, which depends on resolving power. So much for the telescope without lenses.

Now for the spectroscope without lenses. In this case, the prism is put about half-way between the slit and the screen or photographic plate, and since both these distances had to be accommodated within the room† they were necessarily shorter than before. A single flint glass prism of 60° angle was used, and it was necessary to restrict its horizontal aperture to get a definite image of a spectrum line. On the other hand, there is no point in restricting the vertical aperture. The breadth of the horizontal aperture is determined on the same principle as the diameter of the simple image-giving hole which we have already considered. The distance of slit to prism was 8·55 m., and from prism to plate 9·10 m. If the allowable phase discrepancy is $\frac{\lambda}{4}$, taking λ as $5{\cdot}78 \times 10^{-5}$ cm. (yellow lines of mercury), we get for the admissible horizontal aperture 0·226 cm. The prism was put in and the aperture adjusted to give the best separation of the two yellow lines from a mercury vapour lamp. 0·21 cm. was too narrow, 0·27 cm. was too broad. 0·23 was judged best. Thus the expected result is closely confirmed.

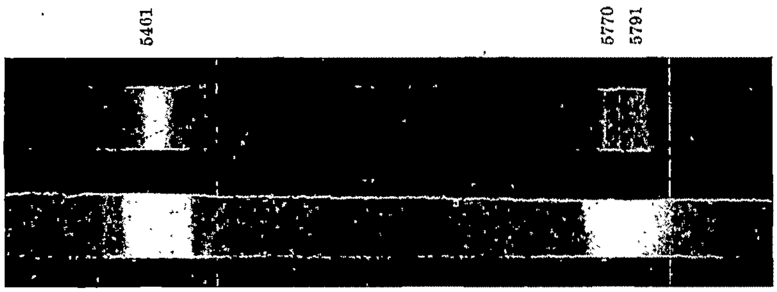


The resolving power of a prismatic instrument is governed, according to the principles given by my

---

* Even a pinhole camera of half this length, with the aperture appropriately reduced, will show the spots fairly well, and allows the whole of the sun's disk to be photographed on a quarter-plate.

† I did not introduce the complication of using a plane mirror to increase the distance.



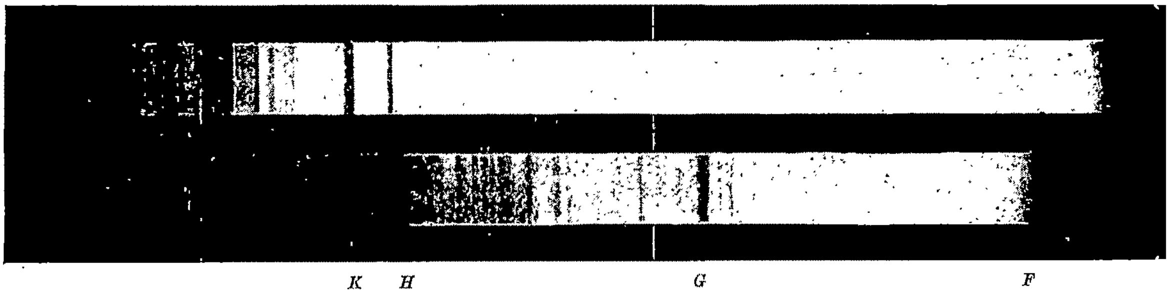
MERCURY SPECTRUM PHOTOGRAPHED WITHOUT A LENS. SUBORDINATE MAXIMA ARE SHOWN IN THE LOWER SPECTROGRAM, WHICH RECEIVED A LONGER EXPOSURE.

father[8], by the effective thickness of the base of the prism, which is supposed to be utilized up to the refracting edge. If f is this thickness, the resolving power $\lambda/d\lambda$ is given by:

$$\frac{\lambda}{d\lambda} = f\frac{d\mu}{d\lambda},$$

where μ is the refractive index. The value of $d\mu/d\lambda$ may be taken as about 1,000 cm.$^{-1}$. In one case with horizontal aperture 0·23 cm., it is about 0·4 cm., which gives $\lambda/d\lambda = 400$ as the theoretical resolving power, while for the mercury yellows $\lambda/d\lambda = 275$. The resolving power should therefore be very adequate to separate them, as experiments confirm.

To get much greater resolving power with a single prism and without a lens would require almost unmanageable distances. Thus it can be calculated that to resolve the D lines would require that the distances from slit to prism and from prism to screen should each be about 56 m. If three prisms had been used instead of one, then the D lines could have been resolved without greater distances than these used in my experiments.



SOLAR SPECTRUM, SHOWING FRAUNHOFER LINES, OBTAINED WITHOUT LENSES. THE UPPER SPECTRUM WAS GIVEN A LONGER EXPOSURE TO BRING OUT THE ULTRA-VIOLET.

In ordinary spectrograms the subordinate maxima bordering on either side the principal maximum of each line are very inconspicuous. In the present case they are much more obvious, owing to the small breadth of the aperture in comparison with the length of the beam. A longer photographic exposure is, however, desirable to bring them out clearly. The subordinate maxima are most conspicuous round the green mercury line, which is brighter than the yellow; moreover, the patterns due to the latter partially overlap. This photograph will make it clear to the eye why linear dispersion is not by itself a measure of resolving power. If we reduce the second aperture the diffraction pattern dilates and the resolving power is diminished, while the dispersion is, of course, unaffected.

The above tests made on the emission spectrum of mercury would lead us to expec
that the Fraunhofer lines coul
be observed with this instrument
In fact, they can readily b
photographed as far as the C lin
at 6563 in the red. The line
are, however, somewhat faint an
diffuse owing to the low resolvin
power not being very adequat
in the visual spectrum. They ar
not easily *seen* on the whit
screen, owing partly to this bu
more to the inadequate brightness, with the light from th
original rather short slit greatl
spread out both vertically and horizontally. Th
lines can be seen better if the distances from th
prism are reduced, say, to about 200 cm. each, an
the prism aperture readjusted to be somewha
narrower. We can then easily see the green line
(magnesium triplet) at 5178, and also F at wave
length 4861 in the blue-green. But the most strikin
demonstration experiment is to receive the extrem
violet on a fluorescent screen as used for X-ray
when the calcium lines H and K at wave-length
3968 and 3934 are very conspicuous, and could n
possibly escape notice. These lines are broader tha
the more visual lines, and at this part of the spectru
the specific dispersion of the glass, and consequentl
the resolving power of the instrument, are muc
greater. The instrument is, of course, astigmati
and the aspect of the spectrum, apart from i
brightness, is in no way altered if a small round ho
is substituted for the first slit.

The photographs of the Fraunhofer spectru
reproduced were on an ordinary (not colo
sensitive) plate. The ultra-violet part is sho
separately because it is best brought out by a long
exposure, which fogs out the visual spectrum. T
distance from the first aperture to the prism was 8
cm. as before, but the distance from the prism to t
plate was reduced to 152 cm. to get the desired ran
of spectrum on to the plate. The second apertu
was reduced to suit this diminished distance, but
will be seen, the resolving power remains adequate.

ROBERT KOCH

FOUNDER OF MODERN BACTERIOLOGY

A HUNDRED years ago, on December 11, 1843, Robert Koch was born. To celebrate his sixtieth birthday, his pupils, among whom were Ehrlich, Gaffky, Loeffler, Pfeiffer, Flügge, Gaertner and Wassermann, arranged a *Festschrift* in his honour and boldly dedicated it to him as the founder of modern bacteriology. A brief review of Koch's life and work will help us to judge whether he is entitled to this distinction and to estimate the significance of his work in the subsequent evolution of the subject.

Without doubt the early period of Koch's career is unsurpassed in dramatic interest, for as an unknown young practitioner in Wollstein, a little out-of-the-way town in Prussia, he carried on his researches, unaided and with the simplest equipment, to such purpose that in 1876–78 he had published three papers, two of which are acknowledged to be classics. He showed for the first time that anthrax is an infective disease caused by a specific bacillus with well-defined characters, and that it is reproducible at will by injecting pure cultures into susceptible animals. There is little wonder that Cohn, who was then professor of botany in Breslau, and Cohnheim, the eminent pathologist, both of them keenly interested in the fundamental but apparently insoluble problems presented by micro-organisms and their relationship to disease, were deeply impressed and were generous in helping Koch to devote his brilliant gifts to the service of humanity. Koch's researches on anthrax were published in 1876 in Cohn's journal, *Beiträge zur Biologie der Pflanzen.* A master of technique, he published a paper in 1877 on his methods. His studies on the etiology of wound infections appeared in 1878; he showed that, when bacteria in putrid fluids are passaged serially through mice or rabbits, the pathogenic varieties can be obtained post-mortem in pure culture and that the lesions are characteristic of the associated bacteria. Koch's interest in the subject doubtless arose from his experiences as an army doctor in the Franco-Prussian War (1870–71). He gave experimental support in this paper to Lister's antiseptic methods, but was unable from lack of clinical material to carry his researches further. The answer was soon supplied (1880–83) in the remarkable contributions of Alexander Ogston, later professor of surgery in the University of Aberdeen, who clearly defined the role of the micrococci in inflammation, and distinguished between Staphylococcus, as he named it, and Streptococcus (Billroth).

A wider field was opened to Koch when, in 1880, he was attached to the Imperial Department of Health in Berlin, where he worked on methods of sterilization and of testing disinfectants. He had quickly realized that, until a simple method of isolating bacteria in pure culture was evolved, progress would be seriously hampered. Methods such as Lister's dilution procedure were too much influenced by chance, and Koch therefore bent his energies towards devising a solid medium, finally utilizing gelatine, which had previously been employed for the culture of fungi, as a solidifying substance; later, agar proved to be more generally useful owing to its special properties. He demonstrated his methods of obtaining pure cultures at the International Congress of Medicine of 1881 in the Physiological Laboratory of King's College, London, with Lister and Pasteur in the audience.

During the early years in Berlin, Koch was fortunate in his chief assistants, Gaffky and Loeffler, who, like himself, were accurate and untiring workers. Within ten or twelve years they, with other pupils of Koch, discovered the causal agents of many important infectious diseases of man.

Koch's discovery in 1882 of the tubercle bacillus, his proof by animal experimentation with pure cultures that it is the cause of tuberculous diseases, and his employment in 1890 of tuberculin as a diagnostic and therapeutic agent, brought him world-wide fame, although the premature publication of his work with tuberculin proved, for a time at least, to have unfortunate results. Again, in 1900 he raised the question of the non-identity of the human and bovine types of the tubercle bacillus, and seemed to be unduly rash in proclaiming his belief that the pathogenic role of the bovine bacillus in man is negligible. Nevertheless, the provocative statement of his views led to an enormous amount of work on the subject in many countries, and perhaps chiefly in Great Britain. At the present time, Koch's old tuberculin has proved to be a valuable reagent and is still extensively used in both medical and veterinary practice. Work on the preparation of a highly purified and stable product based on biochemical analysis continues. The characters of the human and bovine types have now been satisfactorily determined, and it is agreed that in some localities the bovine type can produce the pulmonary form of tuberculosis in a high proportion of cases. The problem of the pasteurization of milk for human consumption bristles with difficulties of a practical kind, but their solution is certain to follow adequate and widespread appreciation among the general public of the issues that are involved.

Koch, in spite of his interest in laboratory technique, took no narrow view of the implications of his work. On the contrary, he well understood that his methods were essential as tools, together with the observations of the hygienist and the epidemiologist, for revealing the obscure paths of infection in outbreaks of disease. Thus on November 28, 1902, in Berlin he gave an address which serves as a landmark in the history of epidemics of enteric fever. His thesis was that the patient or convalescent who continues to harbour the specific germ is the chief source of the infection. At his instigation specially organized laboratories were stationed in the typhoid-ridden localities of Germany, with results which led to a notable reduction in the incidence of the disease and which shed much light on the carrier state.

Koch pursued his researches in many lands. In the years between 1896, at the age of fifty-three, and 1906, he studied sleeping sickness and malaria in Africa, in addition to rinderpest, East Coast fever, and piroplasmosis in cattle: in 1883 he had discovered the cholera vibrio from his investigations in Egypt and India; he was the head of the German plague commission in India; he worked on malaria in Rome; and he advised on anti-malarial measures in New Guinea. This brief statement of the range of his activities shows that he was a microbiologist of wide experience.

Much progress has been made in the thirty years since Koch's death on May 27, 1910, and there have been new and productive lines of research. Thus the related science of immunology has advanced at many points; and the participation of chemists and physicists in the study of bacterial bionomics, in the widest sense of this term, has been a most welcome feature of recent work, and has illuminated many hitherto obscure problems in bacterial nutrition and bacterial metabolism in general. The fresh edifice has been solidly built upon the sound foundations that were laid by Robert Koch nearly seventy years ago. He was truly a master-builder in the domain of science, and it is a sinister and indeed a terrifying aspect of the character of the German people that, owing to ill-founded racial prejudice, their notorious anti-semitic Press should have stooped to disown him, on the ground not that he was a Jew—for this he was not—but that he was a *Judenknecht*, who chose for his intimates such members of the 'hated race' as Cohn, Cohnheim, Weigert and Paul Ehrlich. Detraction of this kind cannot disturb the estimates that have been formed of Koch and his distinguished friends and supporters by the rest of the world, which owes and will ever continue to owe an immense debt of gratitude to these great pioneers of a new science.

G. F. PETRIE.

THE RECENT EARTHQUAKE IN TURKEY

By ERNEST TILLOTSON

EARLY on November 27, 1943 (local time), another very strong earthquake occurred in the region east of Ankara between central Anatolia and the Black Sea coast. The earthquake caused much damage in the towns and villages of Samsun, Osmanjik, Tokat, Herek, Ordu, Amasia and Kastamuni. 1,439 buildings have been reported wrecked and 1,570 damaged, and damage was done to roads, railways and telegraph lines. On November 30 the Ankara radio stated that the deaths caused by the earthquake numbered 2,919. Many thousands more were injured.

At Istanbul Observatory the pulses were so violent that the seismograph was unhinged. At Kew Observatory on November 26, a very strong earthquake was recorded by the north–south, east–west and vertical component seismographs. On the vertical component the primary wave registered impulsively at 22h. 26m. 08s. U.T. and a further *iP* pulse registered on all three components at 22h. 26m. 15s. U.T. The maximum ground amplitudes at Kew were: on the vertical component, 960 μ at 22h. 35m. 47s. U.T. with a period 25; on the north–south component, 1040 μ at 22h. 42m. 35s. U.T. with a period 24; and on the east–west component, 1120 μ at 22h. 46m. 13s. U.T. with a period 25. From a preliminary interpretation of the seismogram the epicentral distance from Kew is estimated to have been 2,970 km., which would be consistent with an epicentre in Anatolia.

From the above evidence it would appear that the epicentre was very close to lat. 41·1° N., long. 35° E., which is north of Çorum and half way between Amasya and Kastamanu, and west of the Black Sea port of Samsun in Anatolia, Turkey. The time of origin of the shock would be near 22h. 20·5m. U.T. on November 26, or 0h. 40·5m. local time on November 27. It appears that the earthquake may have had an epicentral region occasioned by extensive faulting rather than a point epicentre; but if, for purposes of calculation, it is desired to envisage a point focus, this would seem to have been rather deeper than normal.

Strong earthquakes have occurred in this and adjoining regions as follow: 330 B.C., Niksar; A.D. 343, Niksar; 366, Niksar; 499, Niksar and Amasya; 1509, Çorum; 1754, Sivas; 1826, Erbaa; 1827, Tokat; 1875, Niksar, Bereketli; 1877, Mesudiye, Çavdar, Lâdik, Erbaa, Efte; 1890, Niksar; 1895, Çavdar; 1897, Efte; 1899, Erbaa; 1904, Ş. Karahisar; 1906, Reşadiye; 1908, Alucra; 1909, Ş. Karahisar; 1911, Mesudiye; 1913, Reşadiye, Niksar, Almus; 1914, Erbaa, Lâdik; 1919, Almus; 1937, Alucra; and 1938, Kirşehir. But by far the greatest occurred on December 27, 1939, at Erzincan (NATURE, January 6, 1940, p. 13). This latest earthquake mentioned was the forerunner of numerous other smaller shocks which happened throughout the remainder of December 1939 and January 1940, and then major ones on April 14, 1940, July 30, 1940, September 12, 1941, November 12, 1941, a swarm throughout November and December 1941, December 21, 1942, and on June 20, 1943, at Adapazar when 1,304 people lost their lives. Most of these have been mentioned in the "News and Views" columns of NATURE, and there have been scores of smaller shocks at intermediate times from the same epicentra region east and north-east of Ankara.

The present earthquake, though violent, appear to be one of the series which began on December 27 1939. It exemplifies a well-established observationa fact that earthquakes tend to recur in a region onc affected. Whether this is due to the persistence o regional earth-forces and lines of crustal weakness whether it is due to elastic afterworking in the sub crustal layers of the earth, or to the readjustmen of crustal blocks following a large-scale block-faulting movement, is not yet established. One or more o these may be important, and in particular cases othe factors may be fundamental, but whatever the cause it is instructive in view of acknowledged recurrenc to examine past examples.

On April 19, 1938, at about 13 hr., an earthquak occurred in the region of Kirşehir, a village som 140 km. south-east of Ankara. The zone most affecte was between the Delice Irmak in the north-east, th Kiliç Özü in the north-west, the route from Kirşehi to Ankara in the south-west and the depression forme by the Sife Gölü in the south-east*. In the surroundin villages and towns the following percentages o houses were destroyed: Aci, 85 per cent; Efendiköy 82 per cent; Koçbeyli, 82 per cent; Ceritobasi, 81 pe cent, and in other villages smaller proportions. Th epicentral region enclosed within isoseismal 10 wa elongated from north-west to south-east. The principal permanent movement occurred horizontall along a fault, the southerly portion being displace to the north-west relatively to the northerly portio for throws ranging from 30 to 100 cm. The movement along this fault of Akpinar is aligned wit orogenic movement in the region since Mesozoi times, but whether the movement was due to dyin or growing earth-forces is not known.

The earthquake of December 27, 1939, at 2 h (Erzincan) which caused the deaths of some 35,00 people had an epicentral zone stretching fro Erzincan to Amasya and from Carsamha to Artova an area roughly rectangular in shape, 360 km. b 120 km.†. The towns and villages most affecte

[*] Ed. Paréjas-Hamit N. Pamir, "Le Tremblement de terre d 19 Avril 1938 en Anatolie central". Publications de l'Institut Géologie de l'Université d'Istanbul, No. 5, Nouvelle Série, Février 194

[†] Ed. Paréjas, I. H. Akyol, E. Altinli. "Le tremblement de ter d'Erzincan du 27 décembre 1939". Publications de l'Institut Géologie de l'Université d'Istanbul, No. 10, Nouvelle Série, Avril 194

were Tokat, Samsun, Ordu, Giresun, Sivas and Gumushare. In the block-faulting associated with this earthquake, four east–west lines were prominent: (1) the line of the upper Yeşil Irmak; (2) the line of the Kelkit–Deliçav; (3) the line of the Yavlas and middle Yeşil Irmak; (4) the line parallel to the Black Sea about 15 km. distant from the shore.

These lines were in part old orogenic lines, and were called into play again to relieve accumulating stress. Two distinct earthquake movements were observed during this shock. The first was horizontal and the latter, separated from the former by a short interval of time, had a distinct vertical component. With these, but particularly the latter, strong low-pitched rumbling sounds were associated.

OBITUARIES

Prof. H. L. Lebesgue, For.Mem.R.S.

Henri Léon Lebesgue, professor in the Collège de France, a foreign member of the Royal Society and an honorary member of the London Mathematical Society, was born at Beauvais, Oise, on June 28, 1875; news of his death during 1941 recently reached Great Britain.

Lebesgue was one of the greatest mathematicians of recent times, but more of a specialist than most great mathematicians. His work has not the variety and versatility of Poincaré's or Hilbert's; he did not, as they did, enrich almost every branch of mathematics with his contributions. He was rather a man with one outstanding claim to fame. He had other things to his credit; for example, he made one important contribution (the *Pflastersatz* or 'pavement theorem') to topology; but that, and all his secondary work, of which there is not much, is overshadowed by his work on integration. There, he was first: the 'Lebesgue integral' is one of the supreme achievements of modern analysis.

It is no exaggeration to say that Lebesgue remade the integral calculus. The theory of functions of a real variable, of which the differential and integral calculus are parts, has been rewritten since 1900. The revolution had been initiated by Borel, whose famous monograph "Leçons sur la théorie des fonctions" was avowedly the starting point of Lebesgue's researches; but it was Lebesgue himself who took the decisive steps. The older theories of integration, in spite of all that Riemann, Darboux and others had done, were radically defective at several vital points, and in particular in their relations to differentiation. It was not true that differentiation and integration were 'usually' inverse operations, that integration and differentiation, or differentiation and integration, usually restored the original function. Indeed the whole theory was æsthetically unsatisfying; it tended to be cumbrous, long-winded and full of untidy exceptions; and the conservative mathematicians who detested it had a certain amount of excuse for their distaste.

All this is changed; the theory is now one of the most beautiful in mathematics. It unfolds itself in a series of terse and comprehensive theorems, with all the smoothness and elegance of the best 'classical' analysis. In particular, differentiation and integration dovetail harmoniously together. It is a readily intelligible, almost a 'popular' subject, and for this, by the unanimous testimony of every worker in these fields, it is to Lebesgue first that honour is due.

Lebesgue was a fine writer, with an admirably vigorous and lucid style. His two great memoirs, "Intégrale, longueur, aire" (1902) and "Sur les intégrales singulières" (1910), and his two books, "Leçons sur l'intégration" (1904 and 1928) and "Leçons sur les séries trigonométriques" (1906), rank among the classics of mathematical literature. It is sad that the second book should never have been re-edited, since the subject gives perhaps the finest illustration of the inevitability and vitality of Lebesgue's ideas. G. H. Hardy.

Dr. George Washington Carver

Dr. George Washington Carver, the distinguished Negro scientific worker who died at Tuskegee Institute, Alabama, on January 5, 1943, was born of slave parents at Diamond Grove, Missouri, in 1864. He was educated at Minneapolis High School and later at Simpson College, Indianola, Iowa. Graduating in science at Iowa State College in 1894, he proceeded to the M.Sc. two years later. In 1896 he was invited by the late Dr. Booker T. Washington to take charge of the Department of Agriculture at Tuskegee. He discovered on arrival that his duties, apart from administration and normal academic lectures, entailed the reshaping of the entire economy of the district. In fact, he had to conduct mobile classes in the field in order to persuade a despairing and ignorant community that its only salvation lay in adopting a new agrarian economy. The soil, he found, was arid, eroded, unproductive, and the system of farming outmoded. Every farmer in the region was cultivating cotton as a staple crop. Carver's open-air lessons included the cultivation of crops, soil conservation, fertilization, insect control, plant pathology, and the canning and drying of fruits and vegetables.

Carver recognized the necessity for introducing the peanut, *Arachis hypogaea*, and the sweet potato, *Solanum tuberosum dulce*, because soil and climatic conditions were favourable, and the crops were already being grown sporadically for local consumption by large sections of the community. He realized early that the replacement of cotton by peanuts and sweet potatoes was not a complete solution, and that newer and more extensive uses for them had to be found. A long series of chemical experiments culminated in the development of face powder, pigments, paints, stains and ceramic materials from Alabama clays; milk, buttermilk, cream, cheese, condiments, coffee, paper, plastics, stains, insulating boards and more than three hundred by-products from peanuts; starch, tapioca, syrup, coconut substitute, breakfast food, stains, artificial rubber, vinegar and paste from sweet potatoes; paving blocks, insulating boards, rugs, and cordage from cotton. Peanut milk is now being extensively used in infant clinics in areas of tropical Africa where the tsetse fly is endemic.

Carver's scientific achievements have dwarfed his artistic work, but those who have seen his "Three Peaches" at the Luxembourg, or his "Yucca" at Tuskegee, are unanimous in their regret that he had not devoted more time to this department of life. As a man of science, he tenaciously refused to make profits from his inventions and discoveries, and never once took out a patent. It was characteristic of him to decline Thomas Edison's invitation to join his staff, preferring to work in obscurity among the simple folks he had come to know and love so much.

During his life-time, more than sixty books, periodicals and films were devoted to his life and work, and he had delivered addresses at most of the leading universities in the States. Carver was awarded the Spingarn Medal in 1923 for distinguished services to science, and in 1939 he was given the Roosevelt Medal for outstanding contributions to agriculture. The unique position he won for himself in American scientific and social life was marked by the Variety Clubs' award of 1941. This award was made by a national nominating committee of thirty-four eminent editors, publishers, authors and radio commentators, and consisted of a silver plaque commemorating his selection, and an honorarium of one thousand dollars in cash "in token of his sublime service in restoring a multitude of helpless people to happy and productive life through the instrumentality of his brilliant laboratory researches".

Thus grew to maturity and fame, a lad who was once traded for a horse! R. E. G. Armattoe.

We regret to announce the following deaths:

Dr. H. D. S. Honigmann, formerly director of the Breslau Zoological Gardens, and recently scientific adviser to the Dudley Zoo, on November 17, aged fifty-one.

Mr. Geoffrey H. Livesey, a former president of the Royal College of Veterinary Surgeons, and former editor of the *Veterinary Record*, on November 29.

Prof. James Young, O.B.E., formerly professor of science at the Royal Military Academy, Woolwich, on December 2, aged eighty-one.

NEWS and VIEWS

Physical Society: Duddell Medal Award

The twentieth Duddell Medal has been awarded by the Council of the Physical Society to Mr. John Guild, of the Light Department of the National Physical Laboratory, in recognition of his design of a number of optical and physical instruments of outstanding merit. Mr. Guild, who was born on November 16, 1889, was educated at Allan Glen's School, Glasgow, and the Imperial College, London. His instruments are noteworthy for their sound mechanical, optical and physical design and for the scrupulous avoidance of all elaborations that would not contribute to their final precision and accuracy; they incorporate many features that were novel at the time the instruments were developed. The best-known and most important of them are, perhaps, his spectrophotometer (1924), trichromatic colorimeter (1925) and absolute radiometer (1937); but it is difficult to select any one instrument as being more elegant in design than the others, which include a spherometer of precision (1917), a very accurate angle comparator for the goniometry of prisms (1923), a flicker photometer (1923), a vector colorimeter (1925), an improved goniometric spectrometer (in collaboration with the late Mr. George Watts, 1926), a compensated thermopile (1931) and a new instrument for evaluating the surface finish of metals (1940). The Medal will be presented to Mr. Guild at a meeting of the Physical Society at the Imperial College on December 17.

Chair of Geology, Durham: Prof. L. R. Wager

Dr. L. R. Wager, whose appointment to the chair of geology at Durham has been announced, takes with him a distinguished record as a petrologist, an explorer and a mountaineer. Since 1929 he has been lecturer in petrology in the University of Reading, where the efficiency of that section of the Geological Department owes much to his vigorous enthusiasm. While still at Cambridge he had given a foretaste of his ability as a research student in a series of papers on the Whin Sill and part of Connemara. In 1930 he was granted leave to take part in the British Arctic Air Route Expedition to East Greenland, where he made preliminary studies of a peculiarly interesting suite of igneous rocks. In 1933 he was released again to act as one of the climbing party on that year's expedition to Mount Everest. He took part in the first assault, reaching as great a height as has yet been attained. Incidentally, he made many valuable contributions to our knowledge of the stratigraphy and physiography of that part of the Himalaya. On his return to Reading he began to organize a scientific expedition to continue his work in East Greenland, and took a small party which spent twelve months there. The published results of the petrological and mineralogical studies thus made, although as yet incomplete, are works of outstanding scientific importance. Shortly after the outbreak of war he joined the Royal Air Force in a specialist capacity, and held the rank of squadron leader at the time of his appointment to Durham.

Suggested New School of Aeronautical Science

Replying to a question raised in the House of Commons on December 1, the Minister of Aircraft Production, Sir Stafford Cripps, announced that the Aeronautical Research Committee had recommended the creation of a new school of aeronautical science, co-ordinated with existing training facilities, to bridge what it considers to be a gap in the present system. This report is approved in principle by the Government, and an interdepartmental committee has been appointed to prepare detailed proposals for its establishment. The Committee is under the chairmanship of Sir Roy Fedden, sometime designer and chief engineer of the engine section of the Bristol Aeroplane Co. This Company was one of the first in the aeronautical world to initiate an apprentice training school in its works under Sir Roy's guidance, and in addition he has just returned from a tour of the United States, where he has studied the systems of aeronautical instruction in use there.

Although the terms of the report were not announced, it presumably follows the scheme envisaged by Sir Bennett Melvill Jones, the chairman of the Aeronautical Research Committee, in his remarks at a recent discussion upon aeronautical education before the Royal Aeronautical Society. The schoo will be postgraduate and will be additional to the facilities of a similar standard at present available at universities. It will deal with advanced study and experimental work of a technical nature, leaving the more scientific and research aspect to the university schools. It is also hoped to include certain aspect of flying, incidental to the teaching. It is hoped tha such a training will appeal to the university graduat who desires to take up the more applied side of the profession, the works apprentice who has attained a sufficiently high standard in theoretical study, and possibly senior men from the industry and the Forces who desire refresher courses.

A Programme for the Royal Society of Arts

Dr. E. F. Armstrong's inaugural address to the Royal Society of Arts on November 3 entitled "The Long Road of Progress" reviewed briefly the general trend of the Society's activities since its foundation in 1754, commenting on the number of the older societies which regard the Royal Society of Arts as a foster parent. While it is no longer the tradition that the first popular account of any discovery or invention is given to the Society, that tradition is always prominently before the Society in arranging its programme. Discussing the future, Dr. Armstrong urged that the Society should help to form public opinion on housing, on nutrition, and other subjects, through the medium of its members and their friends in a way that the Press, which to-day is largely political and seldom practical, can never do. In addition to lectures, however, it could pursue such projects as raising the artistic standard of the nation, as through its institution of the award Royal Designer for Industry, and its recommendations as to the best training for students intending to design for industry and in art schools in general, and the best methods of selection of young persons for such work.

After a reference to education and to the value of the examinations of the Royal Society of Arts, Dr. Armstrong touched on the question of research and the necessity of having the right kind of men to carry it out efficiently, and the importance of providing the proper facilities. Factories, he emphasized, are worth as much as the ability that directs them and no more, and even in research the head of the department must understand the art of managing men and be able to get along with them and to think as they think. A research department should be changing all the time, so as to bring in young men with ideas. Finally, popular interest in science must not only be maintained, but even increased, if we are to hold our own in the years to come. Whether carried on with Government support or in endowed institutions of learning, the full development of our scientific potentialities depends upon the appreciation of the public. This means continually providing the public with impersonal news regarding scientific progress in all lines of interest to them, from both the material and the philosophical points of view. Moreover, the biggest fight in the post-war world is likely to be for individuality. Science needs tolerance, freedom from restraint and a recognition of the value of individuality, and because it has freed men's minds and helped to free man's soul by broadening the basis of religion, it is regarded by some as the great hope of mankind. We must learn the facts about the environment in which we live if we wish to adjust ourselves harmoniously with it.

Astronomical Work in the U.S.S.R.

Some information about astronomical activities in the U.S.S.R. has been received from Alexander Orlov, formerly director of the Odessa Observatory and now director of the Poltava Observatory, which was built in 1926 for the study of latitude variation and the movements of the earth's pole. When the Germans were approaching Poltava, the valuable equipment of the Observatory was removed to Irkutsk in Siberia, to save it from the destruction that had overtaken the Pulkovo Observatory, near Leningrad. When the Red Army liberated Poltava, M. Orlov returned there, passing through Kharkov *en route*. In Kharkov all the main buildings and cultural institutions were in ruins; of the staff of the Kharkov Observatory, who had not succeeded in escaping before the Germans arrived, some had been killed, some had died of hunger, some were missing and the few who survived were in a deplorable condition. In once flourishing districts of the Ukraine everything had been burnt or destroyed. The city of Poltava had been destroyed with deliberate thoroughness; it had been surrounded and nobody allowed to leave. The Poltava Observatory was damaged, but by chance had escaped destruction. The Ukrainian Government has decided to restore the Observatory as quickly as possible; funds for this purpose, and for a considerable extension of the work of the Observatory, are being assigned. During the past session of the Academy of Sciences of the U.S.S.R. it was decided to open another observatory for latitude-variation work at Komosomlsk, in the same latitude as Poltava. It was also planned to create a central observatory near Kiev, for fundamental observations, analogous to the Pulkovo Observatory.

Functions of the Special and General Libraries

Mr. G. Woledge, librarian of the Queen's University, Belfast, has directed attention, in a letter to the Editors, to a conflict of interests between the small special library and the large general library, which appears to be suggested by the discussions at the ASLIB Conference last September on the international rehabilitation of special library services. Mr. E. J. Carter's paper on the "Rehabilitation Problem and the Service and Technique of Special Libraries and Information Bureaux" and Mr. F. C. Francis's paper on "The British Museum as a Special Library" indicate, indeed, though without explicitly stating so, that the two types are complementary, not competitive, and quite apart from questions of co-operation involved in distribution and dispersion, it is clear both from Mr. McColvin's report on public library service and the more recent statement issued by the Council of the Library Association that the position of special libraries and reference libraries in the general lending library service of Great Britain is receiving attention.

Mr. Woledge acknowledges the immense contribution to research which has been made by the system of inter-library lending through the National Central Library; but points out that there are as yet no accepted principles by which we can determine the complicated question of the desirable minimum of book-resources for the country's research work. Leaving aside altogether the question of the duplication of the most important books—those of which many copies may be in use at the same time in different places and those which are indispensable in any scientific man's library—it is not enough to have only one copy of each book which may be wanted or only one collection for each subject. While the special library has a better chance of completing its collection of the more elusive kinds of literature and can be organized from one exclusive point of view with a specialist and expert staff, the staff of a general library also has its rather different but characteristic expert knowledge, and in so far as it is prevented from specializing is saved from onesidedness. Even from the point of view of research we need general libraries, highly specialized libraries and intermediate collections; libraries from which books can be borrowed and those from which they cannot. The most desirable lines for their development can only be decided after careful examination, subject by subject, of the needs of those who use them. A general survey of Great Britain's needs would, as Mr. Woledge suggests, and has already been strongly recommended as an urgent need in the McColvin report, be of great value in helping to make the best use of available funds, and his warning that funds cannot be unlimited or expended extravagantly is timely. Mr. Woledge scarcely formulates the questions which must be answered before either large or small libraries can take the fullest part in a national system of providing books and information, but he shows that all engaged in library work should consider more closely their functions, not only in relation to special needs, but also to those of the nation as a whole and the contribution they are best equipped to make to national needs.

Radiolocation and Shipping Risks in Peace-time

The fifteenth report from the Select Committee on National Expenditure for the session 1942–43, dealing with the salvage of ships and cargoes, contains important references to developments in radiolocation which seem likely to reduce shipping casualties, and thus to decrease the amount of salvage work to be done in normal times. As a decision on the future use of the large quantity of radiolocation equipment owned by the Government is urgently required, evidence was heard from eminent scientific workers and from representatives of Trinity House on the possibility of using it to increase the safety of navigation after the War under conditions of low visibility. The Committee was assured that much of this equipment would be of value for such purposes, and accordingly it recommends that the Government should examine the question of the post-war use of radiolocation apparatus for safety at sea, together with the making of any international agreements required. The bulk of the report gives an interesting picture of the general salvage position in 1939 and during the War, which does not always reflect credit on the Admiralty. While the Committee resists the proposal to create a monopoly for British salvage enterprises in British territorial waters, unless the hopes of a general breakdown of monopolies and barriers to commercial activity are disappointed, it advances proposals for maintaining British salvage enterprises in so sound and efficient a state that underwriters will not be obliged to call on the services of foreign firms.

The Royal Irish Academy

The meeting of the Royal Irish Academy on November 8 was devoted to a celebration of Hamilton's discovery of quaternions. A well-attended meeting which included Mr. De Valera and other Ministers was addressed by the president, Dr. R. I. Best, who read messages from Prof. G. D. Birkhoff of Harvard and Prof. J. L. Synge of Ohio State University. An account of the Dublin mathematical school in the early nineteenth century with reference to the work not of Hamilton only but also of McCullagh, Lloyd, Jellett, Haughton, Salmon, etc., was given by Prof. A. J. McConnell. Prof. A. W. Conway read a paper on quaternions and matrices in which he showed that the use of quaternion methods makes for great simplification of the meson matrices. A paper by Prof. E. T. Whitaker on the sequence of ideas in the discovery of quaternions and a note on quaternions by Prof. G. D. Birkhoff were also read. A paper by Rev. J. R. Colthurst on the Inconsian calculus of Sir William Rowan Hamilton was read in title. A communication from Prof. F. D. Murnaghan of Johns Hopkins University, entitled "A Modern Presentation of Quaternions", owing to postal delays was received too late for the meeting, but will be included in the report of the proceedings which will be printed.

The Haffkine Institute, Bombay

The report for 1940–41 of the Haffkine Institute at Parel, Bombay, shows a record of widely useful work, of expansion of departments to meet the needs of the War and of increased production of sera, antitoxins and vaccines for the Forces. A new department for the manufacture on a large scale of antitoxins, toxoids and sera has been begun and the Institute has found that it can produce these at a cost one half to one sixth of that of the imported products. The Department of Chemotherapy is also new; it reports that sulphathiazole is effective for the treatment of bubonic plague. Sulphonamide products are being synthesized, their commercial production is being investigated and new compounds in this series are being sought. The production of Haffkine's antiplague vaccine and other work on plague occupy, perhaps naturally, a considerable part of this report. But interesting work is also being done in an endeavour to replace the standard malarial remedies, the supply of which has been reduced by the War. It is claimed that sulphathiazole and another sulphonamide prepared by the Institute have remarkable curative effects on monkey malaria without the relapses which follow the treatment of monkeys with atebrin and quinine.

Poliomyelitis in the United States

According to official information, the incidence of this disease in July reached epidemic proportions in several south-western States, and the figures for the country during the first six and a half months were the highest in twelve years. Figures for the week ending July 17 showed 297 cases in the United States as compared with 245 for the preceding week; 231 cases or 94 per cent were reported from three States, namely, Texas with 102, California with 90 and Oklahoma with 39. For the first twenty-eight weeks of 1943, 1,626 cases were listed for the entire country.

Islands and Peoples of the East Indies

War Background Studies of the Smithsonian Institution, No. 14, relates the story of the East Indies and their inhabitants. The account does not pretend to be other than superficial, but for the intelligent reader wishing to know something about an area that may at any time now come to figure largely in the war news, this book can be confidently recommended. It contains a great deal of information and is beautifully illustrated.

Future of Anthropology

In the discussion on the future of anthropology at the centenary meeting of the Royal Anthropological Institute, as reported in Nature of November 20, there seems to have been a serious misconception of the natural scope of physical anthropology. In my presidential address to Section H of the British Association in 1939, I discussed the subject at some length, and suggested that the future of this important science may be seriously jeopardized if it is not allowed to develop naturally along progressive lines.

Dr. Firth is quite correct in his statement that physical anthropology is a branch of biology, and it may be added that it should therefore be in the hands of trained biologists. It is no doubt due to the neglect of this fact that the subject seems to have undergone considerable stagnation in recent years. The view was expressed at the centenary meeting that physical anthropology is entirely a historical science. Indeed, the writer of the report in Nature goes so far as to suggest that as soon as physical anthropology is applied to practical problems it ceases to be physical anthropology !

This view can scarcely be too vehemently controverted. Physical anthropology is certainly a historical subject in so far as it studies the organic relation of the human species to lower animals, its evolutionary origin, its differentiation into races* and sub-races, and the relation of physique to the different conditions of life in the past. But it is equally certain that it also concerns itself with actualities by the comparative study of living races and their geographical distribution, and by the study of problems of growth and physique in relation to environment and of racial differences in physiological processes. The subject of comparative racial physiology (which is clearly a department of physical anthropology) has hitherto received little attention. Yet its importance must be obvious, and it is not too much to say that the future of physical anthropology will depend almost entirely on its due recognition.

Probably no adequate and complete survey has been made of any native population living under primitive conditions to ascertain from random samples what level of physical efficiency is possessed by its members, how far this is related to inborn racial differences, or to nutrition, climate and other environmental factors. It is important to know to what extent physical efficiency can be improved by higher standards of diet, hygiene and so forth, how human races vary in their adaptability to different environments and different conditions of life, whether there are racial differences in susceptibility to disease or dietetic deficiencies, in ability to resist physical stresses and strains, in relative rates of growth and maturation, in fertility and longevity, in their reaction to extremes of temperature and humidity, etc. We require data regarding the functional efficiency of different physiological systems (cardio-vascular, respiratory, nervous, excretory, digestive, etc.) in different races, and the physical anthropologist of the future must be acquainted with the various physiological and biochemical techniques by which this efficiency can be gauged.

It is scarcely necessary to say that problems of this kind must be answered as a preliminary basis for the social, educational and economic advancement of the more primitive and backward races of mankind, and are thus of considerable practical importance. At the same time, since the physical efficiency of different races must have repercussions on their social and cultural development, it is clear that in the future physical anthropology must keep in close contact with other branches of anthropology, so that the study of mankind remains a properly integrated subject.

If the science of physical anthropology is allowed to follow its natural development along the lines suggested, it will open up a progressive and active field of study which is likely to attract students who are both able and enthusiastic. If, on the other hand, it confines itself to the narrow laboratory study of crania and other parts of the skeleton (a study which is rapidly becoming sterile in spite of new statistical methods) it will soon cease to earn any respect from workers in other branches of anthropology.

Dr. G. M. Morant has pointed out that the three whole-time posts in physical anthropology in Great Britain before the War are now not actively occupied. I would suggest that this provides an excellent opportunity for the complete re-orientation of the subject along functional lines, and that efforts should be made to promote this natural development as soon as possible.

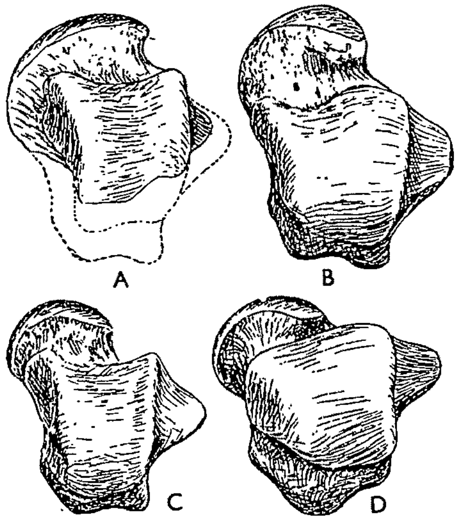
An Ankle-Bone of the Ape-Man, *Paranthropus robustus*

Every addition to our knowledge of the structure of the ape-men of South Africa is likely to be welcomed even though the addition may appear to be a very small one. The Taungs ape, and those discovered at Sterkfontein and Kromdraai, have revealed a group of higher Primates which are very much nearer to man than any living anthropoids, or any of the fossil forms previously discovered. Though the brains are sub-human in size, they are much nearer in structure to that of man than are the brains of the gorilla and chimpanzee, and the dentition is practically human. All the fragments we have of the post-cranial skeleton are so nearly human that had they been found isolated most anatomists would probably have maintained that they were human.

We know the distal end of the femur of the Sterkfontein ape-man, and a perfect os capitatum (os magnum); and of the Kromdraai ape-man we have the distal end of a humerus, the proximal end of an ulna, a metacarpal and a number of phalangeal bones of the hand, and a few toe bones.

In the block of matrix in which the Kromdraai skull lay, there was seen a piece of very badly weathered bone. It looked very unpromising; but when cleaned out it proved to be the most important part of the right talus. The fragment consists of rather more than half the bone, and it shows the greater part of the proximal or upper side. The articular surfaces for the tibia and fibula are nearly



Right talus (astragulus) of (*A*) *Paranthropus robustus* Broom; (*B*) female bushman; (*C*) female chimpanzee; (*D*) a large gorilla. *A*, *B*, and *C* are ¾ nat. size; *D* is ½ nat. size.

perfect, and rather more than the upper half of the distal end is satisfactorily preserved.

In size, this talus agrees fairly well with that of a female Bushman; but in structure the bone differs considerably. The articular surface for the navicular is much broader and more horizontal than in the Bushman, and it extends a little farther inwards than in most human tali.

The articular surface for the tibia and fibula is narrower than in any human tali I can find, and a little differently shaped. A comparison with the proximal articular surface in the talus of the chimpanzee shows considerable resemblance, but the articulation for the navicular in the chimpanzee is very different.

There is very little resemblance between the talus of Paranthropus and that of the gorilla; the tibial articulation being very different.

There cannot, I think, be the slightest doubt that this talus is that of the type *Paranthropus robustus*. The head, jaw, humerus and ulna fragments, the bones of the hand, and this talus are all from one mass of bone breccia less than a cubic foot in size.

The talus is manifestly that of a Primate slightly larger than a chimpanzee. In general structure the bone resembles that of a man more than it does that of any of the living anthropoids, and the little evidence that it brings is in favour of Paranthropus having been bipedal, and of its having had a well-developed hallux.

Paranthropus, though a little less human in its milk molars than Australopithecus or Plesianthropus, is more human in its having a much larger brain.

Paranthropus, in having a brain of about 650 c.c. and a very lightly built body of probably not more than 80 lb. or 90 lb., and in being most probably bipedal, with delicate slender hands, must have been an animal much more like a human being than either the chimpanzee or gorilla. Like the other known Australopithecines, it was certainly not a forest-living Primate, but a being who lived among the rocks and on the plains and hills as the baboons do to-day.

It is hoped that before long a complete work will be issued on all that is known of the Taungs, the Sterkfontein and the Kromdraai ape-men.

Distribution of Colour-blind Men in Great Britain

DURING the past two years the colour vision c many thousands of recruits for the Royal Navy ha been tested by a modified form of the Ishihara an Stilling Tests. Thus for the first time it has becom possible to compare the proportions of colour-blin men in different regions of Great Britain on a larg scale. Significantly greater proportions have bee found to occur in the western than in the easter half of the country. The following table gives th percentages of defectives in nine major areas o Britain, each percentage being based on more tha 6,000 cases. Each percentage has also been adjuste for the lower level of intelligence which occurs i some testing centres than in other centres, since i has been found that men of very low intelligenc tend to do less well at the test.

Area	% Defective	Corrected for intelligenc
N.E. Scotland (Wick, Edinburgh, Galashiels, etc.)	5·37	5·00
London and S.E. (including Chatham, Aldershot and Brighton)	6·81	6·69
East Coast (Newcastle down to East Anglia)	6·99	6·65
Industrial North Central (Chesterfield, Derby, Nottingham, Leeds, Northampton, etc.)	7·43	7·31
W. Scotland and N.W. England (Glasgow, Ayr, Carlisle, Barrow, etc.)	7·72	7·31
Industrial N.W. (Stoke, Liverpool, Manchester, Wrexham, etc.)	7·72	7·41
South Wales and Somerset	7·76	7·41
S. Central (Shrewsbury, Birmingham, Hereford, Oxford, Reading, etc.) ..	8·86	8·65
S.W. England (Portsmouth, Salisbury, Plymouth, etc.)	9·45	9·21

Analysis of variance shows that differences be tween areas are statistically significant, when com pared with variations within areas. The *F*-ratio i 6·19 with 8 and 70 degrees of freedom; a ratio o 3·8 would have a probability of 0·001.

The figures suggest that colour defect may b racially connected with pigmentation, since it i generally accepted that light hair and eyes are mor prevalent in the north and east, dark colouring i the south and west of Great Britain. While no possible in war-time, we hope later to be able t compare our results in detail with figures for th geographical distribution of blonde versus brunett characters.

It should be noted that the total percentage for a areas of 7·49 per cent is much higher than the usua estimate of about 4 per cent for males, simply be cause the test employed is a difficult one which pick out many of the colour-weak, or anomalous tr chromats, as well as the strictly colour-blind.

Instability of Stilbamidine in Aqueous Solution

THE changes which stilbamidine and related com pounds undergo in solution on exposure to the actio of light have received considerable attention in th last two years, and several publications dealing wit the subject have appeared in the literature, fror which it seems that the methods of approach hav been biological and physical rather than chemica Fulton and Yorke[1], Fulton[2], Barber, Slack and Wien and Goodwin[4] have contributed to the elucidation of the changes which occur, and the present position may be summed up briefly as follows. Stilbamidine and, to a rather less extent, its monomethyl derivative, undergo profound chemical change under the action of light, which change is accompanied by a large increase in toxicity, loss of therapeutic activity and disappearance of those properties (characteristic light absorption and capacity for reacting with bromine and permanganate) which are attributable to the ethylenic linkage. The 4 : 4′-diamidino derivatives of dimethyl stilbene, tolane, diphenyl ethane and diphenoxy pentane undergo little or no change on exposure to light.

The explanation proposed by Barber, Slack and Wien[3] to account for these changes in the case of stilbamidine is the addition of the elements of water to the double bond of the stilbene portion of the molecule with the formation of 4 : 4′-diamidino phenyl benzyl carbinol. These authors produce considerable evidence in support of their explanation of the observed phenomena ; but it would seem that they themselves are not entirely satisfied with this explanation, though it certainly accounts satisfactorily for many of the observed facts relating to the changes. They deduce from their observations that the amidine groups are not affected, the change being associated solely with the unsaturated stilbene linkage.

A considerable amount of work has been carried out here both with solutions exposed for long periods to diffuse daylight and with solutions exposed for much shorter periods to direct tropical sunlight, the results of which it is hoped to publish in detail elsewhere. The rapidity with which the primary changes take place on exposure to direct irradiation (insolation in this case), found by other workers, has been confirmed, and observations made here are essentially in agreement with the already published results relating to the disappearance of those properties attributable to the ethylenic linkage. There are, however, reasons for believing that the principal product of irradiation is not the diamidine of phenyl benzyl carbinol, as Barber, Slack and Wien[3] suggest, and an alternative explanation, for which there is some experimental evidence and theoretical support, is proposed below.

As regards the changes which stilbamidine undergoes in solution on prolonged exposure to diffuse daylight, it has been definitely established that the amidine groups are, under these conditions, not stable and undergo hydrolysis and conversion into amido groups with the liberation of ammonium chloride. The primary products of irradiation, which are at least two in number, and the stilbamidine not so converted all appear to undergo this slow hydrolytic process, so that old solutions contain a complex mixture of compounds which, with a few exceptions, do not show wide differences in chemical and physical properties. Two, at least, of these hydrolytic products have been isolated and characterized with fair certainty, namely, 4-amido : 4′-amidino-stilbene monohydrochloride (most probably the trans-form) and 4 : 4′-diamido-stilbene. There is reason to believe that, under our climatic conditions, *cis*-stilbamidine is one of the primary products of irradiation, and that it, and the products of its hydrolysis, persist in solution throughout the consecutive processes of the fractionation of the chlorides and of the sulphates of the constituents of old solutions. The presence of ammonium chloride in these solutions has been confirmed, and there is evidence that adsorption of the stilbamidine base, and other bases, on the glass, and base-exchange, play an important part in these hydrolytic processes. It is quite probable that they are dark reactions.

Further hydrolysis of the amido groups with the formation of ammonium carboxylate groups could take place, but there is at present no evidence that this has occurred under the conditions of neutrality which these old solutions maintain.

It appears from the literature that, although the most frequent behaviour of geometrical isomers on irradiation involves partial conversion of the more stable configuration (usually the *trans*-form) into the less stable configuration, other courses which may be followed are the addition of the solvent at the double bond and polymerization, which latter may be a straightforward dimerization, as in the case of the cinnamic acids, which can dimerize to form truxinic and truxillic acids. This last course seems to be common with ethylenic derivatives of fairly high molecular weight.

There is experimental evidence, as yet by no means conclusive, that under our conditions the principal primary product of the insolation of stilbamidine in aqueous solution is a dimer of stilbamidine, and not diamidino phenyl benzyl carbinol, and that *cis*-stilbamidine is also formed to some extent. The dimer would be 1,2,3,4-tetra (4′-amidino phenyl) cyclobutane, and its anhydrous salts would have the same composition as the corresponding anhydrous salts of stilbamidine. The dimerization— if it occurs —may be of the original stilbamidine or of the *cis*-modification of stilbamidine, which may be the true primary product of irradiation. The kinetics of the reaction, which it is hoped to examine in detail shortly, may throw light on this point.

The above view of the changes brought about in stilbamidine by the action of light allow of some interesting deductions to be made. The dimerization of stilbamidine, in either the *cis*- or *trans*-form, should, from the point of view of steric hindrance, be able to take place more readily than should that of the mono-methyl derivative, and much more readily than that of the dimethyl derivative, which agrees with the observed differences in behaviour of these compounds on irradiation. Fulton[2] himself was not entirely satisfied with his explanation of the difference in behaviour of these compounds and would, one suspects, have preferred to have been able to attribute the difference to steric hindrance.

What may be a more important inference is that a compound of similar structure to stilbamidine, but without its tendency to undergo either *cis-trans* isomerization or polymerization, may have all the therapeutic qualities of stilbamidine—which are undoubtedly good—with none of the disadvantages which attend the latter in practical use, particularly in the tropics. The diamidino derivative of 2-phenylindene, namely, 2-(4′-amidino phenyl)-6-amidinoindene, should be such a compound. By virtue of the *ortho*-ring closure this compound must have the equivalent of the *trans*-configuration, similar to stilbamidine, while at the same time conversion to a *cis*-modification is out of the question. Furthermore, from considerations of steric hindrance, this compound is unlikely to be able to undergo any significant degree of polymerization similar to that which it appears may occur in the case of stilbamidine and its monomethyl derivative. The indene derivative depicted above is, in effect, a 'frozen' form of 4 : 4′-

diamidino monomethyl stilbene. If this compound can be synthesized, examination of its therapeutic activity, toxicity and stability in solution under the influence of light is likely to yield results of considerable theoretical and practical interest.

Transmission of Susceptibility to Carbon Dioxide to Species Hybrids in Drosophila

L'Héritier and Teissier[1] have described a stock of *Drosophila melanogaster* the flies of which die when exposed for five minutes to carbon dioxide at temperatures between 1° and 23° C., whereas other flies of the species recover from such treatment after a few minutes[2]. This susceptibility, S_{CO_2}, or its normal counterpart, resistance to carbon dioxide, is transmitted to the offspring as one unit, but it is not fixed to any of the chromosomes and therefore cannot be regarded as a Mendelian character. In crosses between flies from L'Héritier's stock and normal flies, susceptibility to carbon dioxide is transmitted to the whole offspring by the mother, but only to part of the offspring by the father. Some of the latter's susceptible daughters, but not the sons, may in turn transmit it to their offspring. No individual resistant to carbon dioxide has been observed to transmit susceptibility.

Sturtevant[3] has described sterile hybrids between *D. melanogaster* and *D. simulans*. 10–40 per cent of his crosses *melanogaster* ♀ × *simulans* ♂ produced offspring, predominantly female, but not more than 2 per cent of the reciprocal matings were successful and the offspring from those was predominantly male. From this the conclusion is drawn that hybrids do not survive, unless they carry a *simulans* X-chromosome. Later experiments by Biddle[4] yielded a higher percentage of offspring from the crosses *simulans* ♀ × *melanogaster* ♂, especially when a *simulans* stock containing the mutant black was used.

The above results made it possible to attempt the transmission of the susceptibility to carbon dioxide from L'Héritier and Teissier's original ebony S_{CO_2} stock (*D. melanogaster*) to hybrids from this stock and a stock of *D. simulans*, homozygous for the mutant black. The results of these experiments are summarized in Tables 1 and 2.

Crosses were set up in bottles or vials in pairs of five and kept at 25° C. The exclusively male offspring from the cross *simulans b*♀ × *melanogaster* eS_{CO_2} ♂ emerging at this temperature was characterized by its wild-type colour and some deficiencies in bristles, and could thus readily be distinguished from illegitimate offspring, resulting from non-virgin *simulans b* ♀♀. From the cultures containing reciprocal crosses which had to be kept at 20° C. after pupation, wild-type coloured females emerged which showed some roughening of the eyes. No illegitimate offspring occurred in these cultures.

Table 1 summarizes the results of the carbon dioxide treatment of female offspring from eight mass cultures *melanogaster* eS_{CO_2} ♀ × *simulans b* ♂; control flies of the eS_{CO_2} stock always died, *simulans b* and *melanogaster* or + flies survived. Thus the hybrids from at least seven matings, probably from many more, showed susceptibility to carbon dioxide; whether the resistant flies from culture 3 were all descendants from one mating cannot be decided. Many of the susceptible flies from this culture took a longer time to die after treatment than usual.

Table 1. After 5 minutes in 100% CO_2 at 13°–15° C.

No. of culture	Dead	Recovering
1	41	—
2	71	—
3	118	15
4	65	—
5	17	—
6	23	—
7	87	—
8	29	—

Table 2. After 5 minutes in 100% CO_2 at 13°–15° C.

No. of culture	Dead	Recovering
1	19	45
2	3	7
3	34	12
4	34	33
5	6	15

Table 2 summarizes the results of identical treatment of the offspring of five mass cultures *simulans b* ♀ × *melanogaster* eS_{CO_2} ♂, and its figures suggest, although they do not prove, that the offspring from a mating of this type may contain resistant and susceptible flies in varying proportions. This was also observed in the offspring from two successful paired matings, where the proportions of susceptibles to resistants were 10 : 3 and 12 : 9 respectively.

It thus appears that the susceptibility to carbon dioxide of a stock of *D. melanogaster*, as described by L'Héritier and Teissier, can be transmitted to the crosses between this species and *D. simulans*. In accordance with its intraspecific inheritance, the character is as a rule transmitted to all the interspecific hybrids by the mother, but only to part of the hybrid offspring by the father.

Terminology of Nucleic Acids

Altmann (1889) suggested the term 'nucleic acid' for the acidic substance of high phosphorus content which Miescher had isolated from the nuclei of pus cells and fish spermatozoa. Nucleic acid was a very useful biological term so long as it was clear that it referred to material from the cell nucleus; but the subsequent extensive researches on nucleic acids by Kossel and his school, by Levene and by others, were largely chemical, and ignored the question of what part of the cell might be the source of these substances (see Mirsky[1] for literature). As a result o these investigations, the chemistry of nucleic acid became well known; and although no longer a useful biological word in its original sense, the term 'nucleic acid' has to-day a well-defined chemica significance, referring to the natural tetranucleotides

There are two types of nucleic acid; and both are of very wide, perhaps universal, occurrence in ving organisms. The chief chemical difference beween them lies in the carbohydrate part of the ucleotide: in one nucleic acid it is a pentose, *d*-ibose; in the other it is a desoxypentose, *d*-riboesose. The two nucleic acids are therefore called by hemists ribose and desoxyribose. The only biological erms equivalent to ribose and desoxyribose refer to he sources from which the two acids are most freuently isolated. Ribose nucleic acid is called 'yeast ucleic acid', and the desoxyribose type is called hymus nucleic acid'. Since the former was originally btained from yeast plants, while the latter was most adily available from the thymus glands of animals, ne acids are also called 'plant nucleic acid' and 'animal ucleic acid' respectively, with the distinct implicaon, indeed sometimes the direct statement, that ese two terms express the true difference in distribuon of the two nucleic acids in living organisms.

We now know that this is wholly misleading. ibose nucleic acid is not restricted to plant tissues, or desoxyribose to animal tissues; both occur idely in both animals and plants. Indeed both the ast cell and the thymus gland cell undoubtedly ntain both acids. Thus, as biological terms, 'yeast cleic acid' and 'thymus nucleic acid' are to be oided to-day; and some contemporary writers efer to use the biologically quite non-committal rms 'ribose' and 'desoxyribose'.

It seems to us that recent work has made the stinctive distributions of the two nucleic acids clear ough, so that the introduction of a new terminology r biological use is justified. From studies of the ghly specific nucleal reaction of Feulgen, from ehrens' work on the separation of nuclear and cytoasmic constituents of the cell, from the results of otochemical analysis, especially by Caspersson, d from direct analysis by us of chromatin itself, it now clear that desoxyribose nucleic acid is normally stricted to the chromatin of the cell nucleus, and at the chromatin contains none of the ribose type nucleic acid. We therefore suggest that *chromocleic acid* be used instead of 'thymus nucleic acid' a biological term for the substance described emically by the term 'desoxyribose nucleic acid'. is now certain that the ribose nucleic acid, by ntrast, is found either in the cell cytoplasm or in e plasmosome (nucleolus) of the cell nucleus; it not a constituent of the nuclear chromatin itself. e therefore suggest *plasmonucleic acid* as a useful bstitute for 'yeast nucleic acid' and as the biological uivalent for the chemical term 'ribose nucleic acid'.

A Specific Reaction for Ascorbic Acid

ON adding hydrochloric acid to a solution of corbic acid, reversible oxidation with 2 : 6-dichloroenolindophenol and iodine becomes progressively wer as the mineral acid content increases. When e hydrochloric acid concentration reaches 20 per nt in the case of indophenol and 29 per cent in the se of iodine, reduction of the reagent is completely ibited. On diluting the acid mixture with water, e total reducing capacity of the ascorbic acid is restored, and can be titrated with both reagents. This property is exhibited only by ascorbic acid, and, consequently, substances which interfere in the titration under the usual conditions can be differentiated from the vitamin. With certain other reducing substances the rate of reduction of the reagents is somewhat retarded, but reduction proceeds to completion. With orange juice a small titration is observed in the presence of the mineral acid, and the true ascorbic acid content is obtained either by subtracting this figure from the original titration value or by determining the renewed titration value obtained on diluting with water. With fruits and vegetables of high vitamin content (guava, lucerne and parsley) no interfering substance is found to be present.

The method is particularly useful with glucoreductone produced from glucose and hot alkali, as this substance under the usual conditions of titration is indistinguishable from ascorbic acid. By keeping the hydrochloric acid concentration at 20 per cent this reductone can be titrated with indophenol to completion, the pink colour persisting for 20 sec. at the end-point. With iodine in the presence of 29 per cent acid the titration is not accurate. The high apparent ascorbic acid figure produced with metaphosphoric acid extracts of biscuit, to which concentrated orange juice had been added, was definitely proved to be due to a reductone-like substance only.

Thiosulphate can be differentiated from ascorbic acid similarly using indophenol or iodine. Certain modifications are necessary in applying the method to urine analyses. The new technique provides (*a*) a simple method by which ascorbic acid can be identified in solution, and (*b*) in the case of unknown material, fresh evidence as to whether ascorbic acid is the reducing substance present.

A suggested explanation of the phenomenon is that in the presence of an abundance of hydrogen ions ascorbic acid is completely converted into the non-reducing keto-form. On dilution with water, enolization results with a restoration of the reducing capacity.

Anabiosis in a Soil Ciliate

INVESTIGATORS of the microfauna of the soil have frequently remarked upon the rapidity with which active ciliates make their appearance when samples of dried or partly dried soil are moistened for examination in the laboratory. The conclusion has been drawn that these ciliates cannot be in the encysted condition but are capable of remaining active in soils containing a very low percentage of water.

Some light has been thrown on this matter in the course of recent investigations on the bionomics of a little-known holotrichous ciliate, *Balantiophorus minutus* Schew., which has been frequently reported from soil. In agar plate cultures of this ciliate, it was observed that not only could it remain active in very restricted films of water, wriggling between the bacterial masses on the surface of the agar in an almost amœboid fashion, but also that it was capable of passing into a condition of suspended animation.

without the formation of any cyst, when the free water completely disappeared from the agar surface. This phenomenon appears to be comparable with the condition of anabiosis shown by Tardigrada and other animalcules of the moss fauna, and so far as I have been able to discover, it has not previously been reported for any ciliate. In this condition the body of the ciliate has a shrivelled and flattened appearance and shows no signs of life. It is, however, capable of revival within periods of up to three weeks, provided that it is in contact with some moisture-retaining substance, and that the relative humidity is high. Immediately upon the addition of water, the cilia commence to beat, the organism starts to swim about, and in a period varying from ten minutes to an hour it has regained its normal form and activity.

Balantiophorus minutus is thus peculiarly well fitted for life in the surface soil, where the amount of free water is subject to frequent and drastic alteration, and is at all times limited save in water-logged soils. It is not unlikely that upon further investigation other soil ciliates will be found to possess a similar power of temporary resistance to desiccation.

A fuller account of this work is in the course of preparation, and it is hoped that it will appear shortly.

In conclusion, it may not be out of place to remark that *Balantiophorus minutus* shows a similar ability to cause flocculation of the bacteria on which it feeds to that reported in these columns for *Oikomonas termo* by Hardin[1] and for Epistylis and Vorticella by Pillai and Subrahmanyan[2].

Hitherto Unidentified Absorption Bands of Water Vapour

IN 1912–13, F. E. Fowle[1] made studies of the absorption of infra-red radiation by water-vapour at 0·93 μ, 1·13 μ and 1·47 μ, in order to determine spectroscopically the total water-vapour content of the atmosphere. The first two wave-lengths are at the centres of the ρ and φ bands; the last is about 450 cm.$^{-1}$ from the ψ-band centre.

Recently, studying the rotation-band of water-vapour numerically, I found a striking difference in absorption near the band-centre and at the wing. Assuming a line-width 0·4 cm.$^{-1}$, I found that, to increase the absorption from 20 to 80 per cent, a 25-fold increase in the quantity of absorbing vapour is needed near the band-centre, but a 40-fold increase is needed near the wing. Fowle's results indicate a 25-fold increase at each of the three wave-lengths. This suggests that the absorption at 1·47 μ may be due to a hitherto unidentified band, centred near 1·47 μ. It is, in any event, improbable that the ψ-band should give absorption more than 450 cm.$^{-1}$ from the band-centre, when the much stronger band centred at 6·3 μ extends, on the long-wave side, only 400 cm.$^{-1}$ from its centre.

Mecke's empirical formula[2] suggests that the new band is the band $\nu_3 + 2\nu_2$ ($\nu_\sigma + 2\delta_\pi$), centred about 1·455 μ. To test this, energy-levels for $\nu_3 + 2\nu_2$ were estimated roughly by extrapolation from Nielsen's data[3] for ν_2, $2\nu_2$, ν_3, $\nu_3 + \nu_2$, and those of Randall, Dennison, Ginsburg and Weber[4] for the rotation-band. These gave rough positions for the important lines in the band, which were found to be about 5 cm.$^{-1}$ below the positions of lines observed in sunlight by Abbott and Freeman[5]. The computed energy-levels were increased by about this amount, when it was found that all strong lines predicted between 1·44 μ and 1·48 μ were actually observed, and no others. This establishes the correctness of the identification. The lowest energy-levels are tabulated below.

0_0	6876 cm.$^{-1}$	2_0	6978 cm.$^{-1}$	3_0	7096 cm.$^{-1}$
1_1	6922	2_{-1}	6961	3_{-1}	7055
1_0	6918	2_{-2}	6945	3_{-2}	7022
1_{-1}	6899	3_3	7222	3_{-3}	7019
2_2	7031	3_2	7221		
2_1	7030	3_1	7113		

The new band has evaded detection so far becaus of its weakness, which makes it hard to observe i the laboratory, and its proximity to the ψ-band Other weak bands can, probably, also be identifie in sunlight. The lines observed by Langley[6] a 2·115 μ and 2·1645 μ are probably the maxima o the two wings of the 'butterfly' band 3 ν_2, and th lines found by Abbott and Freeman[5] between 1·178 and 1·21 μ probably arise from the band $\nu_3 + 3\,\nu$ centred near 1·192 μ. Each of these bands is, howeve overlapped by stronger bands, which have hithert masked their presence.

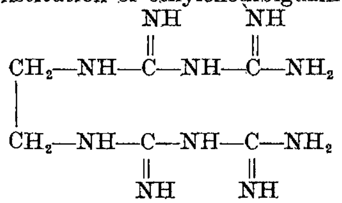
Composition and Constitution of Ethylenebiguanide

IN a previous note on "A New Type of Comple Silver Compounds with Tervalent Silver"[1], the con position of ethylenebiguanide was represented as th given by Dittler[2] as well as by Dübsky and c workers[3]. This is, however, not correct. It has no been found that the so-called ethylenebiguanide, prepared by us following the method described Dittler and also by Dübsky and co-workers, is real an ethylene dibiguanide, En(BigH)$_2$, of the con position $C_8N_{10}H_{16}$. It behaves as a quadridenta molecule with four points of attachment to the ce tral silver atom instead of being bidentate like t so-called ethylenebiguanide. This difference was n detected before, as we had no reason to suspect t composition of the compound and satisfied ourselv only with the estimation of nitrogen and sulpha in a sample of the substance, which, however, agre with those given by Dübsky and co-workers. subsequent estimation of carbon and water both the substance under discussion and in its compl silver salt revealed this difference; 2 $C_4N_5H_9.H_2S$ gives almost the same values for nitrogen a sulphate as $C_8N_{10}H_{16}2H_2SO_4.1{\cdot}5H_2O$.

Therefore, the constitution of the tervalent silv complex should now be represented as:

$$[\mathrm{Ag^{III}En(BigH)_2}]\ X_3,$$

and the constitution of ethylenedibiguanide as :



$$\begin{array}{l} \mathrm{NH}\mathrm{NH} \\ \,\|\| \\ \mathrm{CH_2—NH—C—NH—C—NH_2} \\ | \\ \mathrm{CH_2—NH—C—NH—C—NH_2} \\ \,\|\| \\ \mathrm{NH}\mathrm{NH} \end{array}$$

Surface 'Memory' in a Carboy

Toward the close of a recent afternoon, we calibrated a cleaned, dry 5-gallon carboy by pouring in successive litres of distilled water. During the next morning, we found that the bottom 13 litre-levels had been 'remembered', these levels being precisely marked by the lines of gas bubbles shown in the photograph. We had not previously encountered the phenomenon, nor have we seen it described.

The gas released must have been carbon dioxide. At the time, the *p*H of our distilled water could be ncreased from 4·7 to 6·8 by boiling. Furthermore, the bubbles marking most of the levels were 'fixed' as continuous white lines, presumably of barium carbonate, when dissolved barium hydroxide was added to the undisturbed carboy.

Several successful attempts to reproduce the phenomenon gave some clues to its mechanism. Successive litres of water were poured into each of several carboys through extended funnels, about 10 seconds being required for the pouring and 2 minutes for the filling of the graduate. While this was going on, gas bubbles rose from the floor of the carboy to the surface of the water. Owing to a gentle swirling motion, the smaller bubbles occasionally came into contact with, and adhered to, the walls. During the 2-minute interval, enough pin-point size bubbles were usually captured by the walls to give an almost continuous line marking each level below the topmost. Such lines could usually be seen while the next litre of water was being poured in ; at least once, however, they did not appear until some time later, perhaps because the bubbles adhering were initially so small as to escape observation. The bubbles eventually grew to a diameter near 1/8 in., whereupon they escaped into the gas space over a period of days. Those marking the upper levels disappeared first, probably because the buoyant force acting on them was greatest. (Disappearance of the bubbles owing to re-solution of the carbon dioxide seems less likely.) The phenomenon was observed also in a carboy the walls of which had been wet before the experiment was begun.

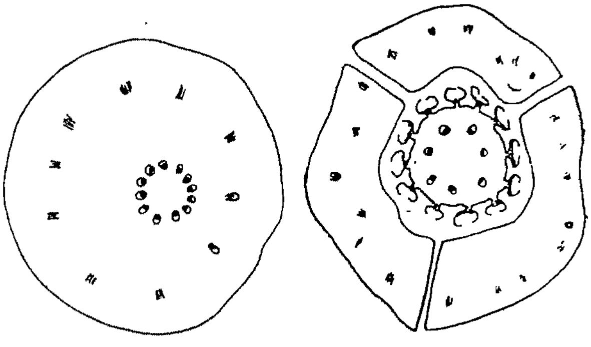
Origin of the Trimerous Perianth

The trimerous perianth being one of the characteristic features of the monocotyledons, its origin is an important problem of floral morphology. Salisbury[1], from detailed studies of meristic variations among the floral parts of the Ranunculaceæ and Helobiales, has come to the conclusion that trimery is really the most primitive condition among the angiospermous flowers. The pentamerous whorl, according to him, has evolved from two trimerous whorls by the fusion of one member of the outer and one member of the inner whorl. A study of the vascular anatomy of the male flowers of *Myristica fragrans* Houtten, Fam. Myristicaceæ, however, leads to a quite contrary view. This family is phylogenetically not far removed from the Ranunculaceæ and is usually included among the Ranales. Its diœcious flowers possess a tubular or campanulate perianth, which divides above generally into three lobes. The serial transverse sections of the male flowers of *Myristica fragrans* show that the trimerous perianth is supplied by ten vascular traces (Fig. 1). Such a vascular supply is clearly of a pentamerous whorl.



Myristica fragrans
1, transverse section of a male flower showing ten perianth traces ; 2, the same at a higher level after division of the perianth tube into three valvate segments. In the centre is the anther-bearing column.

There is thus in this case evidence that the trimerous perianth has been derived from a pentamerous whorl. How the change has occurred is not shown so definitely, but the size of the perianth-lobes points the way. Two of the perianth-lobes are much larger than the third (Fig. 2). This suggests that each of the larger lobes has been derived from the fusion of originally two separate perianth leaves. The persistence of the original pentamerous vascular supply even after the establishment of the trimerous condition in the perianth also favours the view that the change has been brought about by the fusion of certain parts rather than by the suppression of two members.

RESEARCH ITEMS

Salmon of the River Shannon

Arthur E. J. Went has continued his researches on Irish salmon (*Proc. Roy. Irish Acad.*, **49**, Sect. B, No. 9; 1943). The work was undertaken in order to ascertain the differences in the stocks since the completion of the great dam at Partean on the River Shannon in 1929, which marked the beginning of a new stage in the history of the river as a habitat for salmon. After a few years the stocks of salmon in the river had decreased considerably in consequence of the construction and early operation of the hydro-electric plant. Apart from this decrease in numbers, which was of considerable importance both biologically and commercially, there is ample evidence that the characters of the stocks have also changed within the past twelve years or so. In 1940 a new fishing weir, known as the Thomand Weir, was completed, and this provided satisfactory facilities for the collection of suitable material for study. The incoming populations of the years 1927 and 1928 were compared with those of 1941. The incoming populations of 1941 were well conditioned and differed little from the pre-1929 runs. The following differences were found in the 1941 stock: average age of the smolts somewhat higher; a much larger proportion of grilse in the total runs; a much larger proportion of the total catch taken in June; total age of the fish more than a year less, three-year old fish predominating instead of four-year olds; and a considerable decrease in average weight due to the greater proportion of grilse.

Australian Freshwater Mollusca

Tom Iredale has produced a "Basic List of the Freshwater Mollusca of Australia" (Contributions from the Australian Museum, Sydney, N.S.W., *Australian Zoologist*, 10, Part 2; 1943). This is a sequel to the list of land Mollusca previously published in the same journal. The fundamental idea is to determine the relation between shell and environment. The shell characters vary much according to habitat. The study is of undoubted value, for many of these snails might serve as hosts for economically important parasites, especially trematodes. Some systematists may doubt whether the introduction of so many new generic and specific names can have any useful purpose, and they will hope that such names are not generally adopted without the most careful consideration.

Polyploidy in the Red Algæ

In the Floridean red algæ, in addition to the usual haplobiontic and diplobiontic types of life-cycle, using the terms suggested by Svedelius, a few species bear sexual organs and tetrasporangia on the same filaments. In *Spermothamnion Turneri* (Mert.) Aresch., Miss Drew (*Ann. Bot.*, 7, 25; 1943) finds sexual organs on tetrasporic and on normal haploid plants, and also on the haploid individuals degenerate sporangium mother cells. Since sex cells occur on haploid and diploid plants, the carposporophyte may be diploid, triploid or tetraploid; the diploid and triploid carpospores are viable, but tetraploid plants have not been recognized. The only previous case of triploidy in a member of the Florideæ was reported by Drew in 1939 in *Plumaria elegans*, where the plants are maintained by paraspore production. In *Spermothamnion Turneri* the triploid plants do not appear to fit into the life-cycle, though some evidence suggests that tetraspores may be formed on them. Miss Drew has studied this species in Great Britain and at Wood's Hole, and triploid plants have been found on both coasts. It is of interest to recognize these cases of polyploidy in Florideæ, and cytological investigation of other aberrant types should prove of interest. Such studies also emphasize the ability of plants of this group to produce similar plants and reproductive organs irrespective of the cytological condition of the tissues.

Sweet Clover Hybrids

W. K. Smith (*J. Hered.*, **34**, 134; 1943) finds that the sweet clover hybrids *M. alba* × *M. dentata* are chlorophyll-deficient and soon die. By grafting these hybrids on *M. officinalis* they were raised to maturity and a few seedlings obtained by backcrossing the hybrids to *M. alba*. These backcross progeny are also weak, but it may be possible to transfer by this novel method the coumarin-free character of *M. dentata* to *M. alba* and thus provide a valuable economic plant. It is interesting to note that there appears to be stock-scion incompatibility between some plants of *M. officinalis* and the hybrids.

High Rate of Mutation

K. Mampell (*Proc. U.S. Nat. Acad. Sci.*, **29**, 137; 1943) finds that the progeny of a pair of *Drosophila pseudo-obscura* Race *B* had an abnormally high rate of mutation. About 2,000 mutations and nearly all types of characters have been found. A gene 'mutator', probably located on chromosome II, appears to be responsible for the increased mutation-rate. When heterozygous, the rate is 34 times that of the normal rate, and when homozygous it increases the rate 70 times: there is a linear response to loss of gene. The significance of such gene effects in evolution is important.

Instrument Transformers

In a paper on this subject read in London before the Institution of Electrical Engineers on November 19, A. Hobson discusses ratio and phase-angle errors and means whereby improved accuracies may be obtained. Section 1 describes a new method of reducing current-transformer errors, using a compensator which may be either an integral part of the transformer or a separate unit for use with an existing transformer. The compensator employs normal design principles and does not depend on highly critical conditions such as saturated cores. Very high accuracies are obtained, and standard transformers may be constructed having almost unmeasurably small errors over the whole current range, using the most sensitive testing equipment. In Section 2 a method of testing voltage transformers is described in which the Arnold current transformer equipment may be adapted for this purpose. The set measures the difference in error between a standard and the test transformer. Section 3 deals with the estimation of the errors of three-phase star/star voltage transformers at their working burdens, from the results of tests at unity-power-factor burdens. Two methods are given, the first using the six phase-to-neutral test results usually provided by manufacturers, and the second, in which no three-phase calculations are involved, using the results of twelve special tests i three phases are to be loaded or of six tests if only two phases are to be loaded.

Stellar Continuous Spectra

A PROTRACTED investigation of the continuous radiation emitted by stars has been conducted in France during the last decade by MM. Barbier and Chalonge and their collaborators. The work was finished just before the German occupation and the results have apparently been printed in *Annales d'Astrophysique* (**4**, 1; 1941). A corrected proof has now reached the United States, and an article by J. L. Greenstein (*Astrophys. J.*, **97**, 445; 1943) summarizes the authors' conclusions, and reprints in full their numerical results. The measurements were made on the energy distribution in the ultra-violet spectra of 204 stars, mostly of the early types, and are given in the form of two spectrophotometric gradients φ_1 and φ_2 for the regions to the red and to the violet of the Balmer limit respectively. Zero points for the observed gradients were obtained by comparing the spectra of the stars with the continuum given by hydrogen discharge tubes, which were themselves frequently compared with standard filament lamps. The tabulated gradients have an average probable error of about $\pm 0 \cdot 04$ for spectral types earlier than *G*0. Also tabulated are the values of the discontinuity *D* in the logarithm of the intensity on crossing the Balmer limit: on the average, these have probable errors of $\pm 0 \cdot 01$. The mean gradients for 17 normal *A*0 stars are given as $\varphi_1 = +1 \cdot 00$ (colour temperature 16,500° K.) and $\varphi_2 = +1 \cdot 39$ (colour temperature 10,500° K.), the uncertainty here being of the order of $\pm 0 \cdot 10$ owing to the great difficulty experienced in accurately comparing the blue hydrogen tubes with the reddish filament lamps. Several variable stars were studied, and the effect of interstellar absorption on the shape of the energy distribution curves of reddened stars is discussed. The results throw doubt on the λ^{-1} law of interstellar absorption, which had been thought to be fairly well established. The paper concludes with a valuable table giving statistical data (φ_1, φ_2, *D* and their standard deviations) for normal stars arranged according to spectral type.

Movements in Chromospheric Eruptions

M. A. ELLISON has used his spectrohelioscope at Sherborne during the past two years to collect information on the lateral and vertical movements of chromospheric eruptions (*Mon. Not. Roy. Astro. Soc.*, 103, 1; 1943). 187 measures were made, on twenty-two eruptions, on the average at three-minute intervals, and the means show a red-shift for all values of line-width lying between 1·75 and 5 A. The red-shift is intimately connected with the growth and decay of each eruption, and is not inherent in the bright hydrogen from which the eruption is generated. Various reasons are given to show that a Doppler interpretation is very improbable, and it is suggested that the red-shift is an effect of asymmetry in the contour arising from increased absorption on the violet side of the emission line. On the supposition that the eruption is a centre from which matter capable of producing absorption is being expelled, it is probable that the amount of this matter and also the absorption produced by it will increase with the line-width and intensity of the eruption in accordance with the observations. The growth and decay of line-width during the progress of ten eruptions show that there is the same general sequence for all eruptions, namely, a rapid rise to maximum brightness and line-width is followed by a slow decline, the durations of rise and fall being in the ratio of about 1 to 4. In 95 eruptions there were no cases where lateral movements could be detected with any certainty. Where there were apparent lateral movements a satisfactory explanation could be found either by outward diffusion or by the fading of one part of the bright emission followed by an increase in brightness of an adjacent part.

Photographic Observations of Comets at Riverview College Observatory

D. J. K. O'CONNELL has described the results of the photography of five comets, Comet Finsler (1937*f*), Comet Kozik-Peltier (1939*a*), Comet Cunningham (1940*d*), Comet de Kock (1941*c*) and Comet van Gent (1941*d*) (*Mon. Not. Roy. Astro. Soc.*, **103**, 4). The instruments used were a 6¾-in. lens (focal length 130 cm.) and a 4-in. Ross-Grubb-Parsons lens (focal length 46 cm.), and, except for the plate of Comet van Gent, the telescope was guided on the comet. The plates were measured on the measuring machine at Mount Stromlo Observatory, by permission of Dr. Woolley, and the reduction was made by a method described by Dr. Comrie (*J. Brit. Astro. Assoc.*, **39**, 203; 1929). Each plate was reduced with two sets of three comparison stars, and a table gives the results of each solution, together with the comparison stars and their respective dependences.

Gradients and Colour Temperatures of γ Cassiopeiæ

D. L. EDWARDS has described the results of colour-temperature observations at the Norman Lockyer Observatory of γ Cassiopeiæ from June 1938 to October 1941, using objective-prism spectra of δ and γ Cass. (*Mon. Not. Roy. Astro. Soc.*, **103**, 4). Although the comparison star, δ Cassiopeiæ, is a variable, the range of magnitude is only 0·07, and it is probably of Algol type, so there seemed to be no reason why it should not be used for a gradient comparison, and it is probably devoid of temperature variation. The instrument used was the 12-in. McClean prismatic camera, stopped down to 4 in. to give convenient exposure time, and adjusted to give the spectrum in good focus at regions near $H\alpha$ and $H\gamma$. The instrument has a dispersion of about 32 A./mm. at $H\gamma$. Fast panchromatic plates which were specially made for the purpose were used, and these were sensitive to approximately 7000 A. The results are shown in a table which gives the gradient difference between the two stars in the sense γ-δ, after correcting for atmospheric extinction, the absolute gradient of γ, and the corresponding colour temperature, this latter being obtained by assuming the point 1·00 for the Greenwich zero. There is at first a fairly rapid decrease of gradient, implying an increase in colour temperature, and this continued until April 1939, after which there was a sudden change, with a slight average increase followed by a further fall in absolute gradient to a minimum in February 1940, when the temperature reached the high value of more than 24,000°. An interesting relation exists between gradient and the number of Balmer emission lines in the spectrum during one stage of the star's outburst, but this relation does not appear to be permanent. Various changes in the spectrum accompanied the gradient changes, a few of which are mentioned, but a detailed description of these will be dealt with in a later paper.

BINOCULAR AND UNIOCULAR THRESHOLD OF VISION

By Dr. MAURICE HENRI PIRENNE

Psychological Laboratory, University of Cambridge

It has been recently discovered[1] that, on account of the quantum nature of light, there occur at the absolute threshold of vision fluctuations of a purely physical nature which are large enough to account quantitatively for the variability of the response of the organism to the stimulus. The large magnitude of these fluctuations is due to the extreme smallness of the number of quanta which are active at the seat of action of light upon the nervous system, that is, which are actually absorbed by the retinal rods (5–14 quanta as an upper limit). Thus at the threshold, the magnitude of the physical stimulus varies at random from one trial to the next even when conditions are kept rigorously constant. Variations in the sensitivity of the organism may also occur, but clearly the physical fluctuations dominate the situation.

This of course refers to the uniocular threshold. Now, as regards the binocular absolute threshold, which is known to be slightly lower than the uniocular[2], the random nature of the stimulus variability suggests the following possibility. Defining the brightness threshold as the brightness at which the probability of seeing the light flashes is, for example, 0·50, we may ask whether the binocular is not lower than the uniocular threshold simply because the probability of receiving one stimulus of sufficient magnitude is greater when the subject is using two eyes than when he is using one, the two eyes acting as independent light detectors. It must be remarked here that "the fact that with two eyes there is a greater probability of the test field being seen than with one eye" has already been stated by Crawford[2] as an explanation in general terms of the small difference between binocular and uniocular absolute thresholds which he observed under static conditions, but the idea does not seem to have been further elaborated.

Experiment No.	Observed frequency of seeing			p_B calculated	$f_B - p_B$	σ
	Left eye	Right eye	Both eyes (f_B)			
I.	20/50 = 0·40	23/50 = 0·46	75/100 = 0·75	0·68	+ 0·07	0·047
II.	2/50 = 0·04	10/100 = 0·10	13/100 = 0·13	0·136	— 0·006	0·035
III. log. brightness = 1·1	11/25 = 0·44	8/25 = 0·32	14/25 = 0·56	0·62	— 0·06	0·10
log. brightness = 1·4	21/25 = 0·84	22/25 = 0·88	25/25 = 1·00	0·98	+ 0·02	0·028
IV. (pilocarpine)	6/25 = 0·24	10/27 = 0·37	12/25 = 0·48	0·52	— 0·04	0·10
V. log. brightness = 1·0	25/126 = 0·198	71/275 = 0·258	62/164 = 0·378	0·405	— 0·027	0·038

Measurements recorded on one horizontal line were made at one brightness level.

The numerator of the fractions is the number of flashes seen, the denominator is the total number of flashes tried: for example, in I, with the left eye, 20 out of 50 flashes were seen.

Each experiment was made at one sitting, except experiment V (see text).

Log. brightness = 1·0 (arbitrary units) corresponds to an actual test field brightness of 0·0047 e.f.c.

I have made experiments to test the above hypothesis in the particular case of the threshold of a small peripheral region of the dark-adapted eyes. The conditions resembled those used in the investigation by Hecht, Shlaer and Pirenne[1]. The circular test field (opal glass, 10′ in diameter) was placed 20° below a fixation point; it could be illuminated with white light for durations of 4 milliseconds. In each experiment the frequency with which the subject saw the flash with the left, with the right and with both eyes, at one or several brightness levels, was recorded. The natural pupils were generally used. When pilocarpine was used to contract the pupils to a fixed size, the results were similar in nature, as can be seen from the accompanying table.

According to the suggestion formulated above, theoretical calculations of the frequency of seeing with both eyes in terms of the frequency of seeing with the left and with the right eye were made. Let p_L, p_R and p_B be the probabilities of seeing with the left, with the right and with both eyes. Assume that the probabilities p_L and p_R are independent. It then follows from the definition of probability that

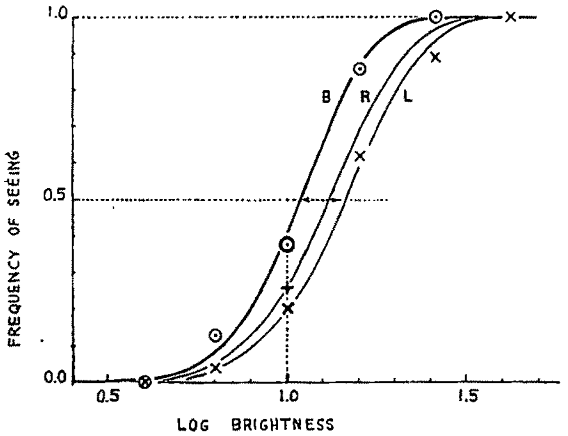
$$p_B = 1-(1-p_L)(1-p_R) = p_R + p_L - p_L p_R \qquad (1)$$

As an approximation to p_L and p_R, the observed frequencies of seeing with the left and with the right eye were used. The fifth column of the table contains the values so obtained. In a series of n flashes the standard deviation of the frequency of seeing to be expected theoretically on the basis of random variations is equal to $\sigma = \sqrt{p(1-p)/n}$. The values of σ are given in the last column of the table.

The table summarizes a number of experiments made on various dates. In experiments I to IV it is seen that the differences between the observed binocular frequencies f_B and the calculated values of p_B are of a magnitude to be expected according to the values of the standard deviation σ. The conclusion to be drawn, therefore, is that, within the experimental error, the facts agree with the hypothesis stated above. It may be pointed out that the reasoning would hold as well if the variability of the response were due primarily to biological, not to physical, fluctuations, provided the probabilities p_L and p_R are still independent.

If complete summation were to exist, the two eyes would behave as a single unit and the same result would be achieved by exposing both eyes to a certain brightness or exposing one eye to twice that brightness. In experiment III it was found that doubling the brightness of the flash in one eye raised the frequency of seeing from an average of 0·38 to an average of 0·86, while the binocular frequency for the former brightness was found to be only 0·56. This rules out complete physiological summation, and shows that the possible amount of partial summation, the existence of which cannot be ruled out because of the inaccuracies of the measurements, must be small in degree.

It is not practicable at one sitting to make enough trials to obtain accurate uniocular and binocular frequency curves. However, in a number of experiments done at intervals during a period of ten consecutive days, it was found that the frequencies of seeing obtained on different days did not show statistically significant differences: the results were accordingly treated as if they had been obtained at a single sitting. Experiment V represents the aggre-



THE THREE EXPERIMENTAL POINTS FOR LOG BRIGHTNESS = 1·0 REPRESENT THE VALUES OF EXP. V. THE OTHER EXPERIMENTAL POINTS CORRESPOND, FOR BOTH EYES, TO 85 FLASHES EACH (EXCEPT AT 0·6, WHERE IT WAS 50); FOR THE LEFT EYE, TO 50 FLASHES OR A FEW MORE EACH (EXCEPT AT 1·62, WHERE IT WAS 28). ⊙ BOTH EYES; + RIGHT EYE; × LEFT EYE.

gate result for the brightness level at which the largest number of flashes was tried. The observed binocular frequency agrees with the calculated one well within the standard deviation, which in this case is less than 4 per cent. Now it was found that the experimental frequency curve determined for the left eye agrees fairly well in shape with the theoretical curve calculated[1] on the basis of the Poisson equation for a retinal threshold $n = 6$ quanta. The same applies to the right-eye curve—the experimental points here have been obtained with fewer trials and are not reproduced in the figure. The following steps were then taken. First, theoretical curves R and L for $n = 6$ were drawn through the two points representing the uniocular data of experiment V. Secondly, the theoretical binocular curve B of p_B was calculated point by point in terms of the curves R and L, using equation 1. Finally, comparing with this curve B the experimental points for the binocular frequency of seeing, it is found that there is good agreement between the two. The data, therefore, fit the theory while making its implications clearer. The figure shows that, notwithstanding the absence of physiological summation, the binocular threshold as defined above is about 0·1 log unit below the mean of the uniocular thresholds. Again, the binocular frequency curve is steeper than the uniocular: the threshold for two eyes is more sharply defined than the threshold for one eye.

Under the present conditions, therefore, the results show that the barrier to be overcome by the stimulation must be situated below the fusion level of the nervous paths of the two eyes. The outcome of the experiments would be the same if the two eyes belonged to different persons, the flash being seen when at least one of the two persons has seen it. The situation closely resembles that found by Sherrington[3] in the case of binocular flicker.

The above, however, may not hold good under different sets of conditions[2]. The investigation will be continued when circumstances allow. Application of the same conceptions to the interaction between different regions of one retina also suggests itself, and is likely to have a bearing on the theory of all frequency of seeing curves.

I should like to thank Prof. F. C. Bartlett, Prof. E. D. Adrian, Dr. W. A. H. Rushton and Dr. K. J. W. Craik for their constructive criticisms. The apparatus used was purchased by the Medical Research Council. I am much indebted to Prof. Bartlett for the hospitality he gave me in his laboratory.

PARASITOLOGY IN FREE CHINA

A TYPEWRITTEN copy of *Acta Brevia Sinensia*, No. 4, edited by the National Science Society of China (editor, Mr. Chentze H. Wu, Department of Physiology, College of Medicine, National Central University, Chengtu, Szechwan) has reached us by courtesy of the British Council. It contains an interesting article by K. Chang on parasitological research in free China.

Until recently, says the author, there was no medium in free China for the publication of original research in parasitology, and investigators in Szechwan have been cut off from the literature and have worked under very adverse conditions. Little has been done in the past on the parasites and parasitic diseases of man and animals in north-west, south-west and west China. Malaria has been a scourge in parts of south-west China, and the China-Burma Highway has aggravated the importance of this problem. American and other workers have studied it during the present War and have concluded that malaria is endemic in south-west China and that the malignant tertian parasite (*Plasmodium falciparum*) is responsible for 15–95 per cent of the cases. *Plasmodium vivax* and *P. malariæ* also occur, and *P. ovale*, described by Stephens in East Africa and thought by some to be a variety of *P. vivax*, has been recorded for the first time from China. *Anopheles minimus* is the chief vector of malaria, but a new species of malaria-carrying mosquito, *Anopheles kweiyangensis*, has been described from Kweiyang by Y. T. Yao and C. C. Wu.

Other protozoological work describes in Pehpei, near Chungking, a disease allied to Tsutsugamushi disease and caused by a Theileria-like organism; an endemic focus of kala-azar in the Sian region of Shensi province; and studies on the rather low incidence of *Entamœba histolytica* (5 per cent) in Szechwan, a curious result in the humid mild climate of this region; in North China with a dry climate and much better sanitation the incidence is 10–25 per cent, which is comparable with the 10 per cent incidence in the United States. Examination of wild rats in Chengtu, Szechwan, failed to reveal *E. histolytica* in them.

Helminthological work includes investigation of the endemic foci of schistosomiasis in Futsing, Fukien Province, and in the Tali-fu region in Yunnan. There is also the endemic area in the Yangtse Valley. Cases also occur in the Chengtu plain of Szechwan.

Fasciolpsis buskii has been found in Kunming, Yunnan, in eleven school-children and in one pig. Studies of hookworm disease show it to be an important problem in Szechwan and in Pehpei, near Chungking. Its relation to some local agricultural practices which favour its spread have been studied. *Hymenolepis nana*, which is not common in China, has been found in 2·4 per cent of persons examined in Sian, Shensi Province. *Trichostrongylus orientalis* has been found to be very common in Szechwan, 50 per cent of persons examined harbouring it in some localities; 11·7 per cent of school-children examined at Chengtu, Szechwan, were infested with *Enterobius vermicularis*. *Ascaris lumbricoides* has been found to be very widely distributed in Szechwan, with an incidence of 84·5–95·5 per cent. The average worm-burden is 8–50 worms, but some children may harbour 100–150 Ascarids. The fertilization of crops grown near houses with night soil is regarded as the most important epidemiological factor; less significant are the eating of raw or partly cooked vegetables and promiscuous defæcation. Under urban conditions pickled vegetables can transmit the infestation. Ascaris eggs were found to complete their embryonation after 60 days immersion in wine, vinegar, sauces, etc.

Finally, the Indian rat-flea, *Xenopsylla cheopis*, which is the principal vector of plague, has been found to be very common in Chengtu, Szechwan. The public health importance of flies is being studied and also the parasites of dogs, cats and other domestic animals.

It is evident that parasitologists of Free China are doing admirable work under very difficult conditions. The sympathy of everyone will go out to them, and practical help should be given from every quarter possible. There must be excellent candidates among them for the postgraduate training established at Cheloo University and the National Kiangsu Medical College. G. LAPAGE.

THE ROYAL OBSERVATORY, GREENWICH

ANNUAL REPORT

THE Annual Report of the Astronomer Royal to the Board of Visitors of the Royal Observatory, Greenwich, deals with the period May 1, 1942–April 30, 1943. Astronomical work at Greenwich has been confined to observations recently re-started on the Airy transit circle, the normal solar work on the photoheliograph and spectrohelioscope, and some special observations of the partial solar eclipse of September 10, 1942, and of certain lunar occultations. The time service, as in the previous year, has been shared between two out-stations, the locations of which are not disclosed. Routine meteorological observations are still made at Greenwich, and the magnetic work continues at Abinger. The Chronometer Depot and the Nautical Almanac Office are also operating away from Greenwich.

Echoes of the War can be detected even in such a report as this. The Nautical Almanac Office has been engaged on computations for the Service Departments to such an extent that astronomical work has been restricted to the minimum required for the continuance of the various almanacs. It needs little imagination to see why work has been recommenced on the "Astronomical Navigation Tables", which are being extended up to 79° N.; while as the result of an extended visit from staff of the Director of Navigational Training (Air Ministry), modifications are to be incorporated in the "Air Almanac" which should make it even more useful to the practical navigator. New editions of the Admiralty magnetic charts have been published, and an analysis of the residuals between observed and computed values of th various data has been undertaken to obtain information about the regions where the chart values ar most uncertain. In the polar areas, where observations are few but where information is needed in war-time, the computed values are used as a guid in drawing the isomagnetic lines. Growing recognition of a close correspondence between solar activity and radio communication is emphasized by the establishment of liaison between the Observatory and certain radio organizations. The estimated times of central meridian passage of large sunspot are now telephoned, for example, to the Radio Research Station of the National Physical Laboratory to the British Broadcasting Corporation, and t Cable and Wireless, Ltd.

It is perhaps in the section dealing with the time service that the matter of greatest general interest i to be found; here certainly the biggest changes ar forecast. It is clear from this report that the Tim Department of the Observatory, partly as a result of increased demands from radio communication services, partly from other war-time needs, is in proces of drastic modification and extension. Experienc with the dual system of operation mentioned above has clearly demonstrated the desirability of providing for two stations as a permanent measure. A Post Office line giving direct communication between the stations for 57 minutes in each hour is now available and greatly facilitates the combination of data. Short-wave signals are now radiated simultaneously with the long-wave rhythmic signals from *GBR*, and of course the 'six dots' service to the B.B.C and the control of the Post Office 'talking clock continue. A modification in the signal transmission procedure has been introduced for the purposes o frequency checking: the rate of the precision signal is now kept as near zero as possible. Should subsequent data show that a signal already emitted is in error (perhaps as the result of a long extrapolation), the correction will be made not gradually but in a jump, the signals then continuing with a zero rate a nearly as possible.

Two fundamental changes in the control of the time service are forecast in the report. The first concern the standard clocks. As has been shown elsewhere (*Mon. Not. Roy. Astro. Soc.*, **103**, 196; 1943), quartz crystal clocks are affected by short-period erratic much less seriously than are pendulum clocks. The occurrence of continual unpredictable changes of rate which, when integrated, produce disturbingly large 'wandering' in pendulum clocks can be greatly reduced by the use of quartz clocks. Prediction of clock error in cloudy weather can thus be made much more certain than it is at present, and it is already the practice to base the time service fundamentally on quartz clocks now established at other institutions, and to use the Observatory pendulum clocks as sub-standards. The report states: "The presen standard of accuracy calls for the elimination o existing pendulum clocks from the operation of the time service at the earliest possible moment". The second change concerns the observational control o the standard clocks: the Astronomer Royal forecasts the supersession of visual time observations on the present standard type of transit instrument. I is believed that a photographic telescope, perhaps o the zenith tube type, should be less liable to accidental errors, and possibly also to systematic errors than the visual instrument.

It is evident that the present trend on the time keeping side of the service is towards electronic rather than electro-mechanical equipment; and on the observational side towards the impersonal photographic plate rather than the over-fallible human senses. As always, the attainment of extreme precision is costing much effort; and if there exists any fleeting regret at the passing of the pendulum, which has served us well for nearly three centuries, it should be allayed by increasing confidence in the last decimal place of the published time-signal corrections.

WAVE GUIDES IN ELECTRICAL COMMUNICATION

AT a meeting of the Wireless Section of the Institution of Electrical Engineers on November 3, a paper was presented by J. Kemp under the title "Wave Guides in Electrical Communication"; this having been published prior to the meeting (*J. Inst. Elec. Eng.*, **90**, Part 3, No. 11; September 1943). With the continuous extension of radio research and application to increasingly higher frequencies, the electrical engineer is already making considerable use of wave guides in place of the more conventional pair of wires or a co-axial cable. The paper under consideration comprises a most valuable survey of the state of published knowledge on this subject and a good introduction for those who have to become familiar with this new technique in the immediate future.

The fundamental theoretical principles of the propagation of electric waves inside hollow conductors or 'guides' have been known for nearly half a century, as a result of the investigations of Sir J. J. Thomson, Sir Joseph Larmor and particularly of Lord Rayleigh, who, in 1897, first dealt with the subject in a comprehensive manner, and established the foundations of the theory on which the modern structure rests. Although Lord Rayleigh's investigations were restricted to hollow metal tubes of infinite conductivity, of unlimited length and of arbitrary cross-section, he was able to show that two distinct classes of waves could be propagated down such a tube. These waves are distinguished by the fact that, in addition to the transverse electric and magnetic forces which accompany the transmission of waves along two parallel wires or a co-axial cable, there is a resultant longitudinal force, which is electric in one case (E-class wave) and magnetic in the other case (H-class wave). Corresponding to the various modes of vibration of a circular membrane or of liquid in a cylindrical vessel, each of the above two classes of wave can be propagated in wave guides in various modes and orders, the essential features of which are described and illustrated in Mr. Kemp's paper.

Up to about 1930, the further investigation of the 'guiding' action of conductors on electric waves was largely confined to the study of transmission line technique or of the propagation of waves round the surface of the earth. Owing to the fact, shown by Lord Rayleigh, that wave-guide transmission could only take place when the wave-length was of the same order or less than the cross-sectional dimensions of the tube, the practical development of the subject had to await the availability of means for the production of very short waves. The paper under consideration shows that, during the past eight years or so, much of the experimental investigation and development of wave-guide technique has been carried out in the United States, notably by G. C. Southworth, S. A. Schelkunoff, W. L. Barrow and their co-workers. All this and other work are summarized in an admirable manner in Mr. Kemp's paper, which describes and illustrates the way in which the various types of waves may be launched into guides, the attenuation and other conditions to which they are subject, and the means whereby they may be converted from one type to another, or may be amplified, detected and received for practical use. In addition, by providing suitably spaced apertures in a wave guide, or by terminating it in a flared horn of suitable size and shape, the wave energy propagated along the guide may be radiated into free space in the form of a concentrated or widespread beam analogous to the emission of longer waves from antenna arrays and reflector systems. Conversely, such horns may be used to receive incoming radiation and feed it into a suitable wave-guide on its way to the radio receiver.

As the author of the paper under consideration points out, the prospective field of application of wave guides embraces various systems of communication, providing telephone and television channels in numbers vastly exceeding those of any system of established type. When used in conjunction with horns, the guides may serve for broadcasting and television, for blind landing of aircraft, for detecting, locating and manœuvring of ships, and for other purposes such as radio telephone links, for which at present radiators and receivers of conventional type are used. The full extent of the field of application of wave guides will ultimately be governed by economic as well as technical considerations, and must therefore remain largely a matter of conjecture; but, judged from the course the development has taken during recent years, it is likely that the field will be large and attractive.

ARCHÆOLOGICAL EXCAVATION IN KASHMIR

DR. HELLMUT DE TERRA has issued an account of his investigations of the megaliths of Bursahom, Kashmir (*Proc. Amer. Phil. Soc.*, **85**, No. 5; September 1942). The valley of Kashmir has been, of course, of the greatest importance in Indian prehistory. It has been a channel through which cultures have penetrated southwards from west-central Asia on one hand and from the Tarim basin on the other. When the early Indus civilization, about which something is now known, thanks to the excavations at Mohenjo Daro, etc., began to wane, cultures from the far north gradually penetrated into northern India, and Kashmir was one of the routes taken by the immigrants. It is to be expected, then, that any early finds in Kashmir might well show foreign influences.

Bursahom is situated on a hilltop composed of pleistocene material, and near by is a megalithic monument recalling in shape a cromlech. Excavation revealed three layers. The uppermost yielded sherds belonging to the Buddhist period of the later Indo-Scythian dynasty of the fourth century. The second cultural level yielded hearths, loose stone foundations and five pits with urns containing the bones of pig and deer. Black burnished ware, decorated with incised geometric ornamentation, occurs. It is suggested that this culture shows influences from north-west or west-central Asia, and that the megaliths probably belong to this period. The oldest culture level yielded hand-made pottery with "textile-and-matt" design, as well as polished celts and bone tools. The pottery shows affinities with that known from Kansu and Turkestan; it suggests an Early Metal Age culture comparable with the Manchang ware culture of Kansu.

Unfortunately, owing to the outbreak of the War and the fact that the finds had to be left at Srinagar, Dr. de Terra has had to depend on photographs and field notes for the description of the objects. But the article is of great interest, and the author is to be congratulated on having found time from his main pleistocene research in northern India to deal with a small but none the less important archæological investigation. M. C. B.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, December 11

British Mycological Society (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 2 p.m.—Dr. S. P. Wiltshire: "The Organization of the Study of Systematic Mycology".

Monday, December 13

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 3 p.m.—Dr. Rudolf Bićanić: "Effects of War on Rural Yugoslavia".

Institute of Fuel (at the Central Station Hotel, Newcastle-upon-Tyne), at 5.15 p.m.—Dr. A. Parker: "The Work of the Fuel Research Board—its Achievements and Objects".

Tuesday, December 14

Royal Society of Arts (Dominions and Colonies Section), (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. G. Martin: "Competitive Rubber Plants".

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—Air-Commodore P. C. Livingston: "The Maintenance of Visual Efficiency in the Royal Air Force".*

Institution of Chemical Engineers (joint meeting with the Chemical Engineering Group and the Institute of Petroleum) (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. J. G. C. Boot: "Petroleum as a Base Material for Chemical Industry".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. A. Fraser Roberts: "Population Problems in the Light of Differential Fertility".

Institution of Civil Engineers (Road Engineering Division) (at Great George Street, Westminster, London, S.W.1), at 5 p.m.—Lieut.-Colonel S. A. McMillion: "The Alcan Highway".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. J. C. Drummond: "Food Problems of the Post-War Years", 4: "Food Education".*

Wednesday, December 15

Royal Society of Medicine (Section of Comparative Medicine) (at 1 Wimpole Street, London, W.1), at 2 p.m.—"The Limitations and Uses of the Comparative Method in Medicine", 2: "Animal Ecology and Genetics" (to be opened by Mr. M. A. C. Hinton, F.R.S. (Ecology), and Dr. H. Grüneberg (Genetics)).

Thursday, December 16

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Prof. W. Perceval Yetts: "Links between Ancient China and the West—a Study of Exchanges in Material Culture", 4: "Northern Nomads as Agents".*

London Mathematical Society (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Dr. B. Segre: "Arithmetic upon an Algebraic Surface".

Lord Rayleigh, F.R.S.: "Pebbles, Natural and Artificial—their Shape under Various Conditions of Abrasion"; Mr. S. L. Smith and Mr. W. A. Wood: "Internal Stress Created by Plastic Flow in Mild Steel, and Stress-Strain Curves for the Atomic Lattice of Higher Carbon Steels".

Friday, December 17

Physical Society (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 4.30 p.m.—Presentation of the twentieth Duddell Medal to Mr. John Guild. Demonstrations.

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 p.m.—Mr. Philip Guedalla: "The Evolution of Air Power".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. N. R. Neal: "Application of Statistical Methods to the Control of Industrial Costs"; Mr. J. C. Edwards and Mr. W. A. Bennett: "Inspection Efficiency"; Mr. A. W. Swan: "Sampling Schemes for Accept-Reject Inspection".

Saturday, December 18

Institute of Physics (Electronics Group) (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. L. Jánossy: "Cosmic Rays".

Royal Photographic Society (Scientific and Technical Group) (joint meeting with the Association for Scientific Photography) (at 16 Prince's Gate, South Kensington, London, S.W.7), at 2.30 p.m.—Exhibition of Scientific Photographic Apparatus.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Second Technical Assistant (temporary) in the Agricultural Economics Department—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Street, Edinburgh (December 14).

Fieldman to assist the Advisory Chemist—The Registrar, The University, Leeds 2. (December 14).

Assistant Master to take Machine Drawing and Design, and Mathematics to Senior National Certificate standard, and Practical Machine Shop Work in the Junior Technical School—The Principal, Wolverton Technical College, Wolverton, Bucks. (December 17).

Assistant Master or Mistress to teach Mathematics and Practical Geometry at the Willesden Technical College, Denzil Road, London, N.W.10 (Junior Technical School of Building)—Dr. E. Davies, Education Offices, Vernon House, 163 Willesden Lane, London, N.W.6 (December 18).

Junior Scientific Officer in the X-Ray and Radium Departments at St. Bartholomew's Hospital—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1 (December 18).

Science Master, mainly for Chemistry, up to University Scholarship standard, at the City of London School—The Town Clerk, 55–61 Moorgate, London, E.C.2 (January 12).

Chair of Chemistry—The Principal, University College of Wales, Aberystwyth (January 15).

Regius Professor of Zoology at Glasgow University—The Private Secretary, Scottish Office, Fielden House, 10 Great College Street, London, S.W.1 (January 17).

Assistant Lecturer for Science and Mathematics (and, if possible, some Physical Training)—The Principal, County Technical School, Halesowen, Worcestershire.

Assistant Master (graduate) for Mathematics, Science and Drawing, at the Aston-under-Lyne Junior Technical School for Boys—The Director of Education, 8 Warrington Street, Ashton-under-Lyne, Lancs.

Technical Assistant and Laboratory Steward for the Department of Botany—The Bursar, University College of North Wales, Bangor.

Laboratory Assistant for the Physics Department—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3.

THE HOUSING OF SCIENTIFIC SOCIETIES

AT a time when plans of reconstruction are being everywhere projected, it was fitting that Sir Henry Dale, in his presidential address to the Royal Society (see NATURE, December 4, p. 649), should put in a claim for more adequate and dignified accommodation for science. Men of science do not require to be told how meanly housed are many of the scientific societies in Great Britain; they can be forgiven a feeling of envy towards their colleagues in other lands where science has been made to enjoy an honoured place in the scheme of national life. It is pertinent to inquire why this should be. We believe that the real root of the matter is that false philosophy which refuses to regard science as a normal way of life in a modern community. To say this does not mean that we claim priority treatment for science; we demand no more than a recognition of the debt which any modern State owes to scientific endeavour.

That this debt is not admitted and honoured may be partly the fault of scientific men themselves. They have sometimes been too prone to seek refuge in a sort of splendid intellectual isolation; they have neglected—some would assert wilfully—the methods of advertisement which art and the drama, music and literature, have employed to stake their claims in the life of the modern State. Speaking a language which is not always understood by ordinary people, they have suffered from being misunderstood; and such a state of affairs is made the easier when the machinery of government and the organs of public opinion—the Press and radio—are guided by men who have too frequently been denied a scientific background to their education.

In general terms, Sir Henry Dale gave some indication of the debt which Great Britain owes to science in war. The Press at once seized upon his words, that to-day the United Nations are superior to their enemies in scientific achievement; the man-in-the-street, had he not read those words, would have been the first generously to recognize that science in war has given life and property a greater protection than was known when enemy bombers raided his towns and cities nightly. At some other time, no doubt, Sir Henry Dale will tell our people how much greater can be the achievements of science in peace, and particularly in those vital years which will follow victory, when great works of reconstruction will have to be carried out on a world-wide basis. Such a pronouncement will hearten all those who have faith in the future.

But the efforts of scientific men to assist in the fabrication of a better world merit a frank admission of the claim for better accommodation for the scientific societies. These societies were founded to enable men of science to meet together to discuss common problems, and the part which they have played in the advancement and dissemination of scientific knowledge is incalculable. The State recognized the importance of the societies in 1778 when it granted the Royal Society accommodation in Somerset House; and Sir Joseph Banks, in his presidential address of 1780, boldly declared that the Society's new home was a "generous recognition by the sovereign of the services which science had rendered to the state". Later, the State admitted the claims of some of the younger societies for accommodation, and still remains in the status of their landlord. We can deplore the lost opportunities of the middle years of the last century, when for a moment it seemed as though London was to be ennobled by a great centre for science. That was one of the grand visions of the Prince Consort; and none was more eager to clothe it with reality than Sir Charles Barry, the architect. The latter's scheme, propounded in 1859, for the development of the Burlington House site, indicates how much London lost by its rejection by the Government of the day. Science lost too; but it is very doubtful whether even Barry's scheme, designed as it was in the grand manner, would have met present-day needs. No one then suspected that the Chemical Society would increase its membership from about 500 to 5,000: as Sir Henry Dale observed, no one then suspected even a future for physics! Increase in membership and better facilities for publication have resulted in an expansion of libraries which was unthought of in the days when the societies moved into Burlington House.

What is the solution? In the first place, the State must be made to appreciate that science has a right to adequate and dignified accommodation in the metropolis. We can but reiterate the words of Sir Henry Dale. "I do not think that we must stand by and allow the claims of science again to go by default. A fear of overstatement, a passion for critical accuracy which is part of the very spirit of science, may make us reluctant advocates. If necessary, however, we must be ready to remind all who may be concerned of the part which the British scientific effort has played in making it possible now to plan at all, with confidence, for our own civic and national reconstruction. But for science, we may remind them, the very different plans which our enemies were so recently making for our future might already be taking effect".

Sir Henry is right in thinking that the claim will, no doubt, be frankly acknowledged: it will certainly be by the ordinary man, but only when he is educated to know more about the nature of the claim. That this can be done has been abundantly proved in the U.S.S.R., where science has a real 'news value' in the Press and over the radio: it is an experiment which might properly engage the attention of scientific men in Great Britain. The scientific societies would not fail to benefit from it.

In the second place, any scheme for the rehousing of the scientific societies must leave room for expansion. The experience of the past has shown us that adequate accommodation to-day becomes inadequate accommodation to-morrow. No doubt a certain amount of rationalization can be effected, for example, in libraries and publication activities, thereby preserving a proper economy of space. But what is imperative is that the State shall immediately tackle this pressing problem. Again to quote Sir Henry Dale: "I think that we have the further right to expect that the home of science, in this capital city, will have a dignity symbolizing its value to the nation and empire, and enabling us to hold up our heads in the company of other countries, whose scientific academies, not more famous than ours, have so long been housed more worthily, and with a more generous recognition of their due place in an enlightened people's scale of cultural values". These are words which ought to be pondered by those who are now engaged in framing a policy of replanning for London.

THE BRITISH SCIENTIFIC INSTRUMENT INDUSTRY

ONE of the immediate results of the harnessing of the whole of the man-power of Great Britain to the war effort has been to engender an almost universal appreciation of the vital part played by scientific instruments in a nation's life. No longer is the scientific instrument an obscure device to be used only by the expert and to be understood only by the specialist. Rather, to the men and women of the factories and of the Fighting Services, it has become a familiar and essential tool, the use of which makes them masters of complicated mechanisms and processes and enables them to achieve, both in the workshop and in combat, a most satisfying degree of precision. The nation has, in fact, become instrument-minded, and this should hearten those who, by the written and the spoken word, have in recent times pleaded for a more vigorous application of science to our national life. For the scientific instrument is one of the main vehicles by means of which the fruits of science are made available to the ordinary citizen, and the general public has, as never before, first-hand evidence of the value of the application of science as it appears concretely embodied in the scientific instrument of daily war-time use.

The circumstances and conditions of the War should have compelled the nation to make the maximum use of its scientific knowledge and of its scientific personnel, and it is not surprising that a belief should have become general that they could be employed equally advantageously when the nation is confronted with its post-war problems even if the nature of these can only be conjectured. In consequence, reports have been prepared dealing with improvements in scientific education, with the provision of the right type of technical personnel for industry, with the necessity of increasing the scale of both academic and industrial research, and with many allied subjects. A point to be observed is that if the high hopes entertained of the adequate use of scientific knowledge in the future are to be realized if research activities are to be markedly increased if the scientific control of industrial processes is to be fully developed, and if scientific education is to be modified so as to provide an effective channel for the infiltration of scientific knowledge into the national life, an adequate supply of scientific instruments suited to each and every purpose, must be available ıe scientific instrument industry should be so proessive in spirit and so efficient in technique as to able not only to meet these potential heavier mands, but also to develop and to produce new pes of instruments incorporating in their design d principles of operation any new phase of scientific owledge of practical application. The moment is erefore opportune to review and to take stock of e scientific instrument industry in Great Britain, d an immediate occasion is provided by the issue a handbook of the Scientific Instrument Manufacrers' Association of Great Britain, Ltd.

It is instructive to be reminded that the early ientific men were their own instrument makers, and at in the seventeenth and eighteenth centuries the storic names of science were associated with instruent invention and production. Many of Sir Isaac wton's investigations were carried out with instruents made with his own hands; the same may be id of Robert Hooke and later of Sir William rschel. It was in these early days of modern perimental science that the origins of the British entific instrument industry are to be found. strument-making firms were established in Newn's time and at an even earlier date, two, at least, which survive to this day. As Mr. R. S. Whipple ints out in an interesting article in the handbook, e increase in the numbers of workers in the scientific ld created a demand for skilled and professional strument makers, but even up to very recent times e experimental scientist evinced a keen interest instrument design and development. One need ly mention the instruments associated with the me of Lord Kelvin and the existence of instrument ms the boards of which, a generation ago, were mposed almost completely of men of professorial nding. New advances in scientific knowledge quently lead to the eventual creation of new types instruments, and one obvious advantage of the se association of the scientific man with the prosional instrument maker lies in the probability at by it the implications of a scientific discovery the field of development will not be ignored for unnecessarily long period. It is perhaps unfornate that in recent years the links between the entific worker and the instrument maker have, in eat Britain, become weaker; in some countries ey have been strengthened. The reputation of itish scientific instruments was never greater than en the great names of science were linked with entific instruments, and the prestige given to the lustry by that association still remains a lively asset.

The pioneer work of British instrument makers ould not be forgotten and can be remembered with ich satisfaction. The science of surveying owes ich to Jesse Ramsden and to William Simms, and at of photography to Andrew Ross and to Dennis ylor. A notable contribution has been made to e development of the microscope and telescope, ile in the science of electrical measurements the mes of Faraday, Maxwell, Wheatstone and Kelvin ll be for ever remembered. Moreover, this pioneer rk was accomplished in the high days of craftsnship, and among the traditions with which a long and honourable past has endowed British instrument manufacturers, none is of greater worth than that of the highest standard of workmanship. While it is true that the quickened tempo of modern industrial life no longer permits the use of methods by which each individual instrument becomes a monument to the craftsmanship of the worker, there yet remains in the manufacture of instruments of precision ample scope for the display of workmanship of the highest quality. During this War, the Services owe much to the compelling force of conservative tradition which has not allowed workmanship in the instrument industry to fall a victim to the claims of production, but has insisted that instruments shall have that distinctive quality which craftsmanship alone can give and that standard of performance so essential in creating confidence in the mind of the user.

The achievements of the industry during the War are too obvious to require enumeration. As has been remarked, there exists a common knowledge of the importance and ubiquity of scientific instruments in both the industrial and the combatant spheres, and the scale of production of instruments is well appreciated. It is a truism that 'instruments are the eyes and the ears of ships and aircraft and the nerve centres of armies and navies in attack and defence'. A special word should, however, be said of the work of the optical instrument industry. The manufacturers of optical instruments are in the unfortunate position of producing goods which are in no sense perishable. The equipment of a laboratory with, say, microscopes, serves not for one, two or even five years, but for a generation. The elderly Service officer even now boasts that his prismatic binoculars served him well throughout the War of 1914–18 and are rendering excellent service in the present one. The size of the optical instrument industry can never be commensurate with the importance of its products, and yet in war-time the demands made on the industry are insatiable. The proportionate minimum requirement for skilled workmen and craftsmen is probably higher in the optical instrument industry than in any other, but in war-time man-power boards are apt in this respect to regard any minimum as largely excessive. In spite of its original limited capacity and of the large dilution of its skill with inexperience, the optical instrument industry in Great Britain has successfully met the demands which have been made upon it, and has done so while still retaining to a very large degree its traditional insistence on good craftsmanship and high instrumental performance. Notwithstanding its inflation, the industry has not lacked adequate British supplies of the various types of optical glass, the quality of which has not been excelled anywhere or at any time. It is appropriate here to pay a tribute to the work of the Inter-departmental Scientific and Technical Committee on Optical Glass and to the wise planning which inaugurated that Committee.

The future of the scientific instrument industry in Great Britain cannot be considered without reference to the closing period of the War of 1914-18. It is generally believed, and hoped, that the circumstances and conditions of the latter half of the year 1918 are reappearing. The immediate future will show whether this be true in the military sphere, but it is certain there was then, as now, a 'stirring of the waters' in regard to the urgency of a greater application to industry of science and its principles, and the same realization of the dependence of such application on an adequate supply and use of scientific instruments. It was at that time that the research association movement of the Department of Scientific and Industrial Research came into being, and the British Scientific Instrument Research Association was formed in that year. Then, as now, an expanded and efficient scientific instrument industry had arisen which had met all the demands of war and seemed capable of satisfying all requirements of the post-war future. It is now a matter of history that the response of industry in general to the opportunity presented by the Government's sponsorship of research was only half-hearted. The instrument industry, and in particular the optical instrument industry, dwindled to its pre-war level, and, more lamentable still, much of the new skilled labour which had been developed within the industry was irretrievably lost.

Into the special conditions, which it is fervently to be hoped will not re-occur, and which resulted in the years following the war being particularly lean ones for the instrument industry, it is not proposed to enter here, nor is it appropriate to consider the measures, involving high policy, which might be taken to prevent their recurrence. Rather will it be assumed that the immediate future will witness a marked evolution in scientific education and a revival of intense research and development activity in industry. In the Report of the Committee of the Privy Council for Scientific and Industrial Research, 1927–28, the following statement occurred: "The British Scientific Instrument Industry occupies a peculiar position. Its direct economic importance is small, but its indirect value is out of all proportion to its size. We shall not be far wrong now in regarding the sales of scientific instruments as a measure of the health of our chief manufacturing industries." This statement is obviously true, although the words "and of scientific progress and education" might well be added to it. The responsibility of the scientific instrument industry to industry in general is apparent and, of all industries, it should be research- and development-minded. Since 1918 the industry has maintained, with assistance on generous terms from the Department of Scientific and Industrial Research, its Research Association, albeit on a modest scale. The Research Association has carried out both basic and immediate investigations into the problems of manufacture of instruments and of the processes employed in manufacture, the results of which have been of great benefit to the industry, and the full fruits of which have been realized during the War.

There is a feeling within the industry, however, that it should maintain a research association which would operate on a scale, not determined by the limited resources of the industry in the past, but rather by the position of high responsibility of the industry. The basic research of such a research association would provide the material on which the developme departments of individual firms would build, to t benefit both of the manufacturing industries and education. It must be remarked, however, that t Services, industry and education each has a respc sibility towards the scientific instrument indust Nothing could be more helpful to the instrume industry than insistent demands made upon it fr outside. These demands should include the pro sion of all types of instruments, adequately to eq British industry with the scientific tools of cont and research, and to give to scientific education added practical value which will ensure that suita trained personnel is available for applied scien Insistence should also be made on the early devel ment within the industry of special instruments special purposes, and of new types of instruments, allow of full advantage being taken of new advan in scientific knowledge.

The handbook issued by the Scientific Instrum Manufacturers' Association shows that the wh range of scientific instruments is covered by industry. The long and distinguished history the industry provides a strong foundation for hope that it will serve the generations of the n era well, and the achievements of the industry in War give an earnest that it can meet the most insist demands made upon it. The future prosperity of nation demands that it shall, in fact, so do.

INITIATION INTO MODERN LOGIC

A Modern Elementary Logic

By Prof. L. Susan Stebbing. Pp. viii+214. (Londc Methuen and Co. Ltd., 1943.) 8*s*. 6*d*.

THE author's aim was to provide a text-bc primarily for first-year students reading lo at the universities. But the reason for that in content and emphasis of her book which differentia it from the usual manuals, and to which the appe tion of modern in its title directs attention, may be immediately apparent to one unacquainted w the change of orientation and the nature of work resulting therefrom which mark the advan ment of the subject since the earliest years of t century.

The source of the difference may be indica very summarily in this way. The scope, purp and content of the discipline traditionally associa with the names of Aristotle and Mill were determi in the main by the conception of logic as bein study of thinking (that is, of judging and inferri or an analysis and criticism of thought, princip concerned to elicit the principles by which vali was secured for those processes. In contrast w this view, contemporary formal or mathemat logicians set aside the thinker and his thinking irrelevant, substituting as the proper 'data' of lo the field of all possible propositions and the relati connecting them. Much as the geometer is said to t for his subject-matter lines, planes, solids, their vari characters and relationships, and not his think about these, so the logician is invited to regar his proper subject-matter propositions and t relations one to another, in abstraction from dging about them or inferring from them. In is way, logic no more than geometry is to be a dy of thinking, and pure mathematics comes to represented as simply an extension or development pure or formal logic. Now this newer orientation d the novel distinctions and analyses traceable to have as yet penetrated scarcely at all into university ching and text-books of elementary logic, and by mposing this "Modern Elementary Logic" Prof. ebbing sought to amend present practice and secure at the new orientation shall be dominant in the st-year course.

Only an experienced and clear-headed teacher ssessed of her mastery of the new work could ve composed within so limited a space an exposition solidly informed and lucidly expressed of the more ndamental parts of the new discipline. All in the ok is admirable that appertains to precision of tement, to relevance and to the order in which e various topics are introduced. But these excel- cies are compromised by two defects in particular, d they are scarcely trivial ones. In the first place, ere is a lack of uniformity in the presentation, nsequent upon the author changing the viewpoint m which she treats her material. Though she heres for the most part to the 'modern' viewpoint hich substitutes proposition for process), she some- nes forsakes it and adopts the 'traditional' one. e objection here is not, of course, that some of e *matters* treated in her book (for example, variations mental attitude in judging; syllogistic reasoning) long to the body of traditional logic. It is that ey are treated in the same *manner* as that in which ditional logic treats them: that is, in a manner ich presupposes the 'traditional' point of view and t the 'modern' one. Consequently we find, not one de of treatment consistently pursued from first last, but two unharmonized modes of treatment; reatment from one viewpoint of certain matters hich have also been traditionally expounded), and treatment from a different viewpoint of other tters (some of which were not expounded in ditional logic). That is to say, she passes from a int of view which presupposes as 'data' nothing t propositions and their relations, to the other int of view which presupposes thinkers and their ntal activities of judging and inferring. To ask ether this inconstancy is symptomatic of anything founder than a blemish in the logical purity of exposition or statement would be to raise a ge issue in epistemology. But it does affect the ok's claim to being 'modern' in the special sense licated, though it will cause no embarrassment to first-year student, nor, provided his examiners 'modern-minded', will it diminish the book's use- ness in preparing him for examination.

This last, however, can scarcely be affirmed of the ond defect to be mentioned; namely, the very dequate space accorded to induction and method- gy. All that the author has to say on this extensive anch of logic is packed into twenty pages, or one nth of the whole book. She admits that her readers ll have to "consult other textbooks" about the tail of induction and methodology. But should t a text-book on logic "intended for first-year dents" comprehend all that is essential for the st-year examination? It is no solution to crush e exposition and illustration of matters that make so much as half the student's whole syllabus into e brief final chapter, and then refer him to other rces for what is wanting. This unwarranted curtailment is regrettable for the further reason that it may only too easily give the beginner the false impression that logic is almost wholly occupied with the demonstrable and certain, and scarcely at all, save in a quite secondary way, with the problematic and its criteria. One inclines to suppose that it is the author's lively interest in mathematical logic that led her to devote so inordinate a proportion of her space to formal doctrine, otherwise the room taken up in expounding a number of technical distinctions that are of no vital concern to a beginner (for example, that between 'entailment' and 'material implication') would have been used to discuss and illustrate more fully what is unquestionably of far greater importance to him.

To sum up: taking the chapters one by one, each certainly succeeds in conveying a great deal of information in short compass and without congestion. But taken collectively, those chapters make up an ill-balanced book. Specialist enthusiasm seems to have been responsible for injudicious selection. However important a contribution to one special department of the subject these Russellian developments may be, it seems undesirable to incorporate them so immoderately in a first-year text-book that they form the bulk of the logic with which the beginner first becomes acquainted.

S. V. KEELING.

ROLE OF VITAMINS IN PLANT PHYSIOLOGY

Plants and Vitamins

By W. H. Schopfer. (A New Series of Plant Science Books, Vol. 11.) Pp. xiv+300. (Waltham, Mass.: Chronica Botanica Company; London: Wm. Dawson and Sons, Ltd., 1943.) 4.75 dollars.

FEW studies in biochemistry have aroused such popular interest as the remarkable advances made in recent years concerning the dependence of animals on small doses of those substances, produced mainly by plants, which we call the vitamins. It is natural that the marked heterotrophy for these substances in man has stimulated interest largely in the vitamin aspects of animal nutrition; but it has always seemed anomalous that the importance of vitamins to the plant which makes them, realized only vaguely even by many botanists, has not had wider publication. This gap has now been filled in this remarkable book, and it is well that the first major review should come from the hands of an expert, and indeed one who may be said to be the founder of the modern science of plant vitaminology. His book is, as it must be, of the nature of a preliminary report on a subject now in the full tide of development; but it tells, in an orderly way, of all the important advances made in the ten years since Schopfer (1934) first showed the necessity for vitamins in the culture of Phycomyces, with sufficient bibliography to enable enthusiasts to find other sources of information. It is further very satisfactory that the author, though not hesitating to reproduce and discuss the structural formulæ of the vitamins and to emphasize the vitally important, if purely chemical, aspects of vitamin structure, does not fall into the trap of making the work biochemical. It is a book written by a plant physiologist for plant physiologists.

Ever since the introduction by Wildiers in 1901 of the concept of bios, plant physiologists have tended to remain aloof, and to explain the apparent necessity for traces of organic growth substances by plants grown in artificial media as due merely to some fault in the composition of the mineral nutrients and organic foods presented to the plants. This is a natural and healthy reaction, and it is clear that some workers on the growth-substance concept have been hasty in their conclusions. Few doubts can remain after reading this book. The author, in the chapter on methods, points out these possibilities of error at some length, and details the many reasons, apart from lack of growth substances, for which a plant will fail to develop on a purely synthetic medium; in fact, he sometimes leans away from the growth-substance concept himself as, for example, on p. 78, where he says of the germination of pollen: "Natural riboflavin is the most active substance on pollen but, since it is contaminated by boron the activity must be attributed to the latter". It is not, of course, clear that all workers adopt the rigorous attitude of Prof. Schopfer, and some of the investigations recorded in this book will scarcely satisfy the reader (for example, the supposed function of asparagine as a cofactor on p. 105), but the careful consideration given to cultural conditions by the author himself leads the reader to accept his opinion with some confidence in most cases.

Experiments have been carried out on very many species at all phylogenetic levels, and in many cases the vitamin requirement worked out in considerable detail by the use of synthetic as well as natural preparations. Auxo-heterotrophy has been demonstrated clearly in many species, among green plants as well as non-green and even in roots of the flowering plant, and is clearly due to a loss of the power to synthesize some essential vitamin. Apart from the very thoroughgoing determination of the necessity for specific vitamins, the author assesses very carefully and logically the bearing of his findings on problems of sexuality in plants, of symbiosis, of parasitism; and many other points of physiological importance are touched upon throughout the book.

The subject naturally divides itself into three subsections, and this division is adopted in the book. Section 1 deals with plants which can synthesize vitamins; Section 2 with plants which cannot; and Section 3 with general physiological problems involving vitamins, of the type mentioned above. In Part 1, after a study of methods, the principal vitamins synthesized by plants are discussed, together with as full an account of their action on plants as present knowledge will allow. In Part 2 follows a detailed discussion of each of the vitamins concerned: thiamin, riboflavin, pyridoxine, nicotinic acid and nicotinamide, ascorbic acid, carotenoids, etc., and their effects on plants which have lost the power of synthesis, as well as a brief excursion into the effects of animal hormones on plants (particularly of œstrone, the only one with any marked effect). The interplay of various growth factors is emphasized in many cases, and special mention may perhaps be made of the useful discussion of the nitrogen-fixing and lactic acid bacteria. The discussion of each vitamin includes the capacity of various plants for synthesis, the specificity of the vitamin and its function in the plant. It is now evident that most, if not all, vitamins operate as coenzymes, or part of coenzyme systems, in the respiratory processes of plants, and this point is well emphasized throughout the book. The third part attempts an analysis of the importance of vitamins in agriculture and horticulture, and a study of parasitism, etc., already mentioned. Lack of precise and wide knowledge makes this the shortest sectio but it is in many ways the most interesting, for shows the way to future fields of great promise. T last chapter is of particular interest to plant physi logists working in related fields, for in it the auth attempts to set up a series of micro-organisms test objects in the study of vitamins.

Apart from a few words of variable spelling (f example, 'thermostabile' and 'thermostable') and o or two sentences the meaning of which is obscure (f example, p. 96, "It is unusual that the fruits riche in carotenoids are frequently the richest in ascorb acid . . .", meaning actually that carotenoids a ascorbic acid are usually associated) the translator to be commended on his performance of a task peculiar difficulty. Prof. Schopfer's book cannot fa to make a wide appeal. His subject is a meeti ground of many specialized sciences—organic chem istry, enzymology, animal and plant physiolog microbiology—and all these meet here to solve pro lems which are fundamental. His book should ther fore be well received as a clear and thoroughgoi exposition of this new field. R. D. PRESTON.

ERATOSTHENIAN AVERAGES

Eratosthenian Averages

By Aurel Wintner. Pp. v+81. (Baltimore, Md.: T Author, Johns Hopkins University, 1943.) 2 dolla

THIS is a curious and interesting little boo though unlikely to appeal to a wide circle mathematicians. The author makes heavy deman both on the intelligence and the knowledge of h readers, and his English, though usually 'correct', English of a very 'continental' type, overpacked wi allusions, parentheses and qualifying clauses. A go deal of allowance must be made for the inhere difficulty of the subject-matter, but it is a pity th he could not write in a simpler and less oracular sty

I will not try to give any reasoned account of t content of the book: a few summary indicatio will be sufficient for any reader sophisticated enou to profit by it. He should be familiar with the ou lines of the classical theory of the distribution primes. He should know the inversion formula Möbius, and the simpler 'Tauberian' theorem 'density' and 'almost periodicity' should mean som thing to him; and he should understand what meant by talking of theorems of different 'depth To such a reader I can commend a book in whi he will find plenty to interest him—theorems new him, and old theorems in unfamiliar settings. If has not this background of knowledge, he would more profitably employed in acquiring it.

The most attractive part is probably Part 2, which the author develops a 'Fourier theory' arithmetical sequences (which includes, for examp the theory of the 'Ramanujan sums'). But sur there should be some reference here to the work Carmichael in Vol. 34 of the London Mathemati Society's *Proceedings*? I should add, in fairness the author, that I have committed the same sin omission myself.

Part 1 (on the 'Eratosthenian matrix') contains interesting discussion of various implications, supposed implications, of the formulæ of Möbi Part 3 (on the 'statistics' of the prime num theorem) is very tough reading, but that is primarily the author's fault. G. H. HARDY.

Microscopic Technique in Biology and Medicine

By Prof. E. V. Cowdry. Pp. iv+206. (Baltimore, Md.: Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1943.) 22*s*.

THIS is decidedly a book for the expert. It consists of an alphabetical arrangement of formulæ, references and short descriptive notes on microtechnical methods, and, as would be expected from its author, it is comprehensive, up to date and well documented. In fact, it is almost too comprehensive, for a number of subjects are included which are only on the fringe of the subject, while on the other hand some of the short articles on methods are so succinct that they suffer somewhat in intelligibility.

The alphabetical method has great advantages in some respects, where such varied material is collected together, but it is rather apt to lead the searcher on a steeplechase across the book when he wishes to get full information on a single subject. Thus "Fixatives", for example, involves sixty-four cross-references. An excellent feature, however, is the printing of all cross references in heavy type, which makes it easy to follow them up.

The first impression on looking into the book is that everything possible is here, but that is going a little too far. The temptation in reviewing such a cyclopædic work is to sigh over the absence of some of the reviewer's own pets, instead of praising the author's actual achievement, but even so, and allowing for the explicit exclusion of plant techniques, it is a pity that there is no mention of Newton's invaluable gentian-iodine technique for chromosomes, and it is surprising that Leishman's blood stain is absent, though it is still widely used.

It would be ungenerous to carp at occasional misspellings and similar trifles, but the reviewer cannot but protest, though humbly, against one more usurpation of the term "Biology" by animal science, in the title of the book. What is wrong with plain "Zoology", when plants are excluded?

Every practising microtechnician will find that this work is one that he will want to keep handy in his work-room. It will be to him of constant and, we hope, of permanent value, not least for the rich store of references it contains.

R. C. McLEAN.

The Diagnosis of Mineral Deficiencies in Plants by Visual Symptoms

A Colour Atlas and Guide. By Dr. T. Wallace. Pp. vi+116+114 plates. (London: H.M. Stationery Office, 1943.) 10*s*. net.

DURING recent years one of the most important advances in relation to the growth of field crops has been the recognition of the important part played by minute traces of elements other than those usually applied as fertilizers. Deficiency of any essential nutrient is reflected in some way in the growth and colour of the plant, and Dr. Wallace has performed a useful service to all agriculturists by collecting and describing a series of one hundred and fourteen colour photographs of various crops showing mineral deficiencies. The aim is to provide a means whereby deficiencies can be recognized and rectified at an early stage of growth, so enabling a full crop to be obtained. A scheme is indicated whereby land of unknown cropping potentialities can be tested by growing a series of indicator plants with various fertilizer treatments, the indicators being selected for their special susceptibility to a wide range of deficiencies. Where a visual diagnosis is doubtful the matter can often be settled by simple methods of spraying, responses to such treatments usually appearing within ten or fourteen days. Special attention has been given to the most urgent questions of war-time production, deficiencies such as copper, zinc and sulphur, which are not known as practical problems in Great Britain, being omitted. The illustrations, with the accompanying diagnostic key, provide a fund of most useful information.

Encyclopedia of Substitutes and Synthetics

Edited by Morris D. Schoengold. Pp. 382. (New York: Philosophical Library, Inc., 1943.) 10 dollars.

THIS "Encyclopedia" is very lavish of space: not only is it set out with a wealth of 'leads' that reminds me of much pre-war practice, but also the diction is in many places unnecessarily verbose. For example, instead of stating that atabrine is slightly soluble in water, there is a sub-heading "Solubility", and well below the words "Soluble in water only to a slight extent". The very wide spacing and the reiterated sub-headings may make for easy finding, but a more compact form of presentation, with some tables of physical constants, etc., would have reduced the size, weight and price of the volume, or allowed of the inclusion of many more uses.

A few curious statements have been noted: in referring to the production of ammonium sulphate by the destructive distillation of coal, it is asserted that "If the ammoniacal vapors are conducted into sulfuric acid and then crystallized and dried, ammonium sulphate of commerce is obtained". Calcium phosphate and calcium sulphate are both described as white powders which are found free in Nature. Despite such blemishes the book will be found useful by all who need up-to date 'potted' information on substitute and synthetic materials. E. H. T.

Dictionary of Science and Technology in English—French—German—Spanish

By Dr. Maxim Newmark. Pp. xvi+386. (New York: Philosophical Library, Inc., 1943.) 6 dollars.

THIS dictionary contains ten thousand English terms that are frequently used in the physical sciences and their applied fields, together with separate indexes in French, German and Spanish, conversion tables and technical abbreviations. The total number of entries, including cross-references, is about fifty thousand. The English part is divided into alphabetical sections (A, B, C, etc.); each word is followed by its equivalent in French, German and Spanish, always in that order, and a number. Parts containing the foreign words follow, each word bearing a letter and a number referring to the English part. An example will make this clear:

Border, chaudière *f.*; Dampfkessel *m.*; caldera *f.* . . . [354].

Chaudière, B354;

and similarly for the German and Spanish words.

This arrangement saves an extraordinary amount of space, in comparison with the arrangement usual in polyglot dictionaries. The pure sciences included are chemistry, physics and some mathematics. Of the applied sciences engineering, in all its branches, is particularly well treated, but meteorology, navigation, and photography also receive attention.

The book is a credit to the institution where it was conceived—the Brooklyn Technical High School.

E. H. T.

ANTHROPOLOGY IN RECONSTRUCTION

By PROF. F. C. BARTLETT, C.B.E., F.R.S.

I MUST confess to a considerable reluctance to repeat, word for word, a lecture which is already printed. I propose, therefore, to attempt a rather rapid summary of the printed form of my Huxley Memorial Lecture* and then to devote my attention to certain problems which could not, in that form, be considered.

I have assumed that anthropology should take a leading interest and share in all future construction or reconstruction of human society, and that if it is to do this it must enter into very much closer working relationships with other scientific disciplines, both physical and biological, than have ever so far been achieved. Further, if the claim that it can do this is to be fully substantiated, anthropology must now, and for some time to come, seek its main data in the empirical and, so far as possible, the controlled study of the behaviour of contemporary social groups.

This view is unquestionably biased and partial. It implies that anthropology is to take over and apply to whole populations those problems of the determination of behaviour and behaviour changes which psychology studies with its eye on the individual. It believes anthropology to be interested, like any other science, chiefly in causal sequences and relations within its proper sphere of study. It accepts the view that one of its primary aims is to be able to say that if any given population is submitted to particular conditions the probabilities are that these will issue in a particular sort of behaviour.

Not for one moment do I wish to suggest that these are the only problems which anthropologists will tackle. There are many others of a historical, descriptive and topographical character which have been a main concern of the subject and will, I hope, continue to be studied vigorously. But I do urge that these, especially as they affect contemporary group-life, are now of paramount importance, and should be given some priority.

The study of man is, and always has been, too vast to be a proper concern of any one investigator, of any one school, or of any one method of approach alone. Whenever it has kept close to empirical fact it has tended to split up into a number of related disciplines of study, of which four are frequently distinguished. They are: (1) physical anthropology or anthropometry; (2) the study of the effects upon group behaviour of general environmental conditions, particularly of climate, natural economic resources, lines of transport, and the size and trends of change of population; (3) the study of the applications of whatever natural knowledge is current within a group at the time at which it is being investigated and of their influence upon behaviour; that is to say, the survey of what is often called 'material culture'; and (4) the study of a group's psychological possessions, its traditions, beliefs, customs, ideals and of their repercussion upon social conduct: that is to say, of what is often, but not very well, called 'social culture'.

It may be a matter of surprise to many that I have given no specific place to archæology. This is not due to any disrespect for a wide and most fascinating field of investigation, but rather because it seems to me that archæology should either be regarded as a subject to be cultivated for its own sake, largely and inevitably descriptive, or else as a line of approach which can be adopted towards any or all of the four main branches of anthropology which I have mentioned.

On the whole, anthropometry has produced somewhat disappointing results. There are many reasons for this, but the primary one appears to be that the bodily characters chosen for measurement have, most of them, no clear and unequivocal relations to behaviour. Particularly behaviour does not regularly vary with simple changes in the size and shape of these characters. I believe that the time has come for a strong attempt to establish a genuinely functional anthropometry in which the leading idea will be to select for measurement only those characters the presence, distribution, or absence of which have a demonstrable bearing upon large-scale social activities.

For example, in the early days of the present War, it became possible to carry out an extensive survey of intelligence levels in a representative section of the population of Great Britain. At the same time, details about professional and industrial occupations were recorded. From the analysis of the results secured it can be stated reasonably accurately what are the probabilities that a person of known age in England in 1939–40 will be found within a particular occupational range. The range is a relatively large one for the middle levels of intelligence and becomes much more restricted at the extremes.

A statement of this kind is psychological. But suppose we could obtain a similar survey of intelligence levels and their distribution, in any comparable group, where new or changing developments in industry were desired, we could begin to predict what industries and professions could reasonably be encouraged within this group. That would be an anthropological statement.

The matter does not stop there. Occupational proficiency depends not only upon intelligence level, but also upon a variety of practical skills depending in their turn upon measurable qualities, or functions, of fingers, hands, arms, legs, lungs, heart, eyes, ears and central control. If we can get—a not impossible task—reliable data about the levels and distribution of these in any population, we can make our predictions of the extent and range to which occupational opportunities can be successfully stimulated within that population more accurate.

Other conditions must be studied as well, and to some of these I will turn in a moment. Meanwhile, one conclusion is inescapable. The measures required for the development of a functional anthropometry are all of them physical, physiological, neurological, biochemical and psychological. To understand the bearing of these measures upon occupation, a clinical, often a directly medical, outlook is demanded. The data are required on a large scale and their distribution is as important as their bulk. Hence the expert statistician must work on them, perhaps developing new statistical technique to do so.

When all this is done, however, from our present point of view, we have got only data and the means of assembling them. The problems remain anthropological. They require people who are able to appreciate key points in large-scale behaviour and how to deal with them. A functional anthropometry which is to be used in the service of anthropology calls now for a development of wider and more intimate team-work than has been achieved or even generally been considered necessary.

---

*Anthropology in Reconstruction. The Huxley Memorial Lecture for 1943. By Prof. F. C. Bartlett. Pp. 8. (London: Royal Anthropological Institute, 1943.) 2s. 6d. The article printed above consists substantially of the lecture as it was delivered.

The study of human functions and their distribution will never give the anthropologist all he wants. Basic human activities may, for example, favour the development of heavy industries. But if climate, economic resources, lines of transport and size and trend of population are separately or together against them, any prediction based upon the anthropometry of the situation is likely to be of little moment. At the same time, the investigation of these general environmental influences demands just the same co-operation of many-sided effort and development of team enterprise. As a result of the stimulus of a world-wide war, for example, much more detailed information is now available about the precise effects of extremes of climate, and, a matter of special importance, of how to counteract, change and direct these, particularly by nutritional agencies. By brilliant scientific discovery, the effects upon group behaviour of immediate economic resources, of lines of transport, and in consequence of the size and trends of populations, have been vastly altered. The discoveries are in part physical and chemical and in part biological. Very often again, they have a strong medical interest. In this sphere also, therefore, a wide development of team-work is needed, so that the best methods may be applied to collect the most reliable and relevant data, and at the same time the significance of the data for an understanding of group reactions may be kept in view.

The story remains unaltered if we turn to the field of 'material culture'. Nothing has changed more rapidly or radically all over the world in recent times than material culture. Nothing has altered the ordinary everyday life of people, for good or ill, more profoundly than rapidly following applications of natural knowledge.

I think that, without giving up its long-established habits of studying very early developments of applied natural science, it is time that the anthropological study of material culture made more serious attempts to understand how the later products in the same line are affecting the lives of men. The physicist, chemist, engineer and biologist are the modern social reformers, though they rarely set out to be, because it is their discoveries which are the most widely applied to produce the quickest results. To understand how science revolutionizes the day-to-day life of man in every region of the world, and to appreciate fully how this influence is likely to be still further extended, once more needs collaboration between the anthropologist and all other natural scientists.

Of all branches of anthropological investigation it will be readily understood that the one which must interest the psychologist most of all is that which has to do with a group's less tangible possessions, with its institutions and their functions, with its customs, beliefs, trends and ideals. We may know all that can be known about levels and distribution of human capacities, about the influence of material culture, and still we shall only imperfectly understand, or be able to foretell, what changes will befall a group, and whether they will be transitory or permanent, until we can know the pattern of psychological possessions into which they must fit. To know this I think the psychologist and the anthropologist, to the great gain of both, must come more closely together than they have ever yet done. The last ten years or so have been a period of intense activity on the part of psychologists all over the world who have been interested in the social aspects of their science. They have invented and applied all kinds of special methods for the collection of evidence of a reliable nature about social attitudes, beliefs, opinions and the like. They have tried to find what forms of question, and what conditions of their application, can be most trusted. We now have an almost bewildering variety of possible lines of approach. There are questionnaires, with many special devices for getting representative samples of replies. There are interest inventories, opinion and assessment scales for rating social attitudes and activities. There are diverse forms of special interview. Prof. K. Lewin and his students, and many others as well, have begun to try experiments with partially controlled social groups. Elsewhere the beginning of a direct experimental attack has been made upon the problem of how, in fact, people anywhere do actually think about social questions. Efforts have been made, though these have usually been anything but sympathetic to psychology, to develop particular ways of observing mass behaviour and mass opinions. Still further removed from any official psychological countenance or free participation have been the tremendous and disturbing attempts to force public opinion and action by organized propaganda. The methods exhibit every degree of control, partial control and complete uncontrol. Almost every one of them has been used to point to conclusions, which have frequently been stated with exasperating dogmatism, and are of a kind that any anthropologist, who usually has a very much wider knowledge of comparative history, can treat with legitimate derision.

Yet derision is only rarely along the way of progress. The methods are here. They will be used. Indeed it is true to say that under the stimulus of a war which has made it necessary to plan for controlled behaviour in very large populations, those people, unfortunately fewer than they might be, who want plans to rest on evidence have turned more to the eager empiricism of the psychologist than to the more widely based and perhaps more dispassionate judgment of the anthropologist. Here then, in the study of social culture, let us work to forge a link, closer than ever before, between these two sciences.

Wherever we turn now we find scientific specialists with methods of ever-increasing accuracy for the establishment of knowledge about the great forces of Nature and their impact upon human kind. It is not surprising if sometimes those who follow this path allow the very intensity of their search and the demonstrable accuracy of their results to tempt them to premature generalizations which anthropologists, with a fairer knowledge of the wide sweep of history, and the enormous divergencies in and of human social groups, can reshape to better purpose.

In this rapid survey I have tried to show that the future for an anthropology which will understand and perhaps help to guide the destinies of man lies in a closer and more friendly relationship with all the special sciences, and particularly with all biological studies. The meticulous and attested knowledge we now must have. There is no escaping from that. Many men will play many parts, each branch of learning maintaining and increasing its integrity while yielding up its isolation.

I have suggested that the study of the distribution of fundamental human activities, of those factors which I have included under general environmental conditions, and of the impact of modern developments of material culture, are all needed in order that we may reasonably estimate, in a rather abstract manner, what kinds of change could occur, or could be planned to occur, in specific groups, as a result of contact. But if these abstract possibilities are to be given any concrete status, they have to be considered in the light of studies belonging properly to social anthropology.

Let me use what may appear to be a somewhat trivial illustration. The people of Great Britain have recently received many invitations—if such they may be called—to change their food habits. On the whole, they seem to have done this with astonishing ease and success, when they have been left to decide how to do it for themselves. I do not know, but I suspect, that if a survey were made it would be found that, under these conditions, while food content has become much more uniform, meal-timing exhibits just as much diversity from one section to another of the population as it ever had. But there are large sections of the public for whom both the content and the timing of principal meals are prescribed pretty rigidly, and naturally the content is, or so it is alleged, determined chiefly by biochemical considerations in relation to economic possibilities, and the timing by industrial ones. Every anthropologist knows that food habits are ticklish things, and that whereas some communities change them with astonishing readiness, others resent and resist change just as naturally. I have no inside knowledge, but for what it is worth my own observation and information lead me to believe that if anybody liked to look into the matter he would find that often, when a noble meal of roast beef, potatoes, cabbage and the like is provided, a substantial proportion of the population for whom it is designed would be found sitting about in or out of their canteen, eating food obtained from their own retailers, and prepared in their own homes. If an anthropologist were asked about this, I think he would say, "First let me carry out a rapid survey of the food habits and their timing of these people, of their regularity and permanence". Then, perhaps, some scheme could be achieved which would satisfy the nutritionist, the economist, the industrialist, the Government officer, the anthropologist, and, most important of all, the people who must eat what is provided when it is ready. For all I know, this may have been done, but it does not appear to have been done on any considerable scale. I wonder why ?

The main reason may be that there is as yet no general recognition of the fact that the speed, permanence and harmony with which any change of culture can be effected, whether it is planned or achieved without any deliberate planning, depend more upon how it is related to what I have called the group's 'psychological possessions' than upon anything else.

If we are to tackle the difficult and intricate problems of what changes are most likely to happen when different cultures meet, we must have some fairly definite guiding ideas. I suggest that a primary aim now should be to search for methods which will enable us to say with some certainty what are the 'hard' and what are the 'soft' points of group or sectional culture. The 'hard' points are those which will resist change, the 'soft' points those which will readily yield and open the way to peaceful reform.

To determine what is now called 'culture pattern', even when this can be done with wide assent, is not enough. A pattern is too independent of its detail, which may change almost indefinitely, at least within wide limits, leaving it recognizably the same. But in the case of culture it is the detail, quite as much as its relation to other details, which presents the obstacle or offers the opportunity.

First, very obvious and prominent differentiating points of contrasting cultures seem to be more often 'hard' than not. But just because they stick out and are possessed by one side only, they are often, especially by the reformer in a hurry, considered to be mere unimportant detail. It is not a bad rule to avoid hitting first and openly at manifestly differentiating points.

Secondly, if one of the four main lines of approach which I have discussed suggests that a specific change may readily occur as a result of contact, it is very tempting to expect, or even to plan, for such change. But this is always misleading evidence. For example, we may demonstrate a reasonable level and a wide dispersion of mechanical abilities in a community and at once set up a system of training suitable to modern highly mechanized industrial life. But if economic, political and social influences are adverse, this will only encounter in the end the hardest of all 'hard' points of culture. For it will set lots of people along some path of purpose and then stop all but the lucky few from reaching the goal Many a partially thought-out scheme of education has foundered on this rock.

Thirdly, although the pattern concept is not by itself enough, it does seem true to say that the hardness or softness of cultural detail does depend on their 'lines of intercommunication' within the community; and it may be hazarded that detail is the more likely to change in proportion as it has some tangible expression which is dissociated from a group's psychological possessions, and less likely in proportion as it has little or no expression in the material side of culture.

To these tentative suggestions I now wish, though in no dogmatic frame of mind, to add one or two more. The social anthropologist who sets out to see methods for deciding hard and soft points in particular cultures is almost at once brought up against historical problems. The psychological expressions of culture usually, maybe always, have roots deep down into the past. How deep must we dig ?

In the strange period of interlude between the two great Wars, psychology has been overrun by the view that everything that happens in human life is determined in and by the remote past. A rapid series of developments are pictured in early infancy, and after that, childhood, adolescence, the prime of life and old age merely succeed in donning a tremendous variety of disguises. Since the disguises are infinite in number, though often stereotyped in character and all represent the same rather unpleasant pattern which is considered to be fixed before and soon afte birth, this is one form, very extreme, of the explanation by culture pattern.

Anthropology has, I believe happily and honourably, escaped the greatest and gloomiest extravagances of this view. But not entirely. There are those who see in every group activity nothing but a disguised repetition of motives, impulses and event first played out in some long-gone cradle of mankind. The present and the future of all group developmen are tied to an unchanging past, and the apparent novelty of their forms is only an illusion. Explanation is a one-way traffic.

I wish to enter a very strong plea for the perfectl naïve study of trends and ideals in social culture. I believe that if these are taken at their face value, and not merely interpreted in terms of archaic symbols and imaginative social origins, they will reveal, perhaps more readily than anything else, the soft and yielding points of any culture. In one way and another the study of man seems to have come into a period in which it is fashionable to treat trends and ideals with suspicion, and the more noble they may appear the more they are suspected. They are treated as tricks obscuring some unchanging struggle between primitive social instincts. It is time to call a halt to all this. There is no great difficulty and I think no great honour in showing that the trends and ideals by which modern social groups are organized have grown out of sorry beginnings. They are none the less achievements, often proud achievements, and if they are considered very simply, as any man of honest common sense will treat them, they can be seen as the pathfinders lighting the way to a knowledge of how cultures that meet will most powerfully interact.

There is another question the answer to which, it seems to me, anthropology, with its wide and minute study of comparative social history, can seek with more promise than almost any other branch of knowledge. This is the question, supremely important at the present phase of human affairs, of the time that may be expected to elapse before changes brought about through social contact can become established. Everybody must have noticed that it seems a lot easier to say what changes are likely to happen when two groups meet than it is to say when they will occur. This may be because, as many people think, the problem is insoluble, except by guesswork, or it may be, as I prefer to think, because it has rarely, if ever, been intensively studied by a combination of experimental and comparative methods and with a full appreciation of the immense influence of modern scientific invention and educational practice.

From the experimental field proper comes at least one glimmer of promise. Innumerable studies have been made of learning processes in animals and man. It is true that in most of these the balance of attention has been towards what is learned rather than towards the time of assimilation and establishment. But times have been plotted with great accuracy, and in the last few years it has become apparent that it *is* possible to state with reasonable accuracy how long it will take many new processes to be established, not only in the individual, but also in the group. Always, I think, the time is longer than the natural optimism of the innovator would like. Both the experiments and their applications have concerned selected groups alone, and so we are very far still from being able to apply the knowledge gained to the unselected and very diverse populations most often affected by culture contacts. But one thing has become very clear. Whenever the new process has to be exploited by a group, working as a group, the material and social possessions of that group, as they are when the process is introduced, must be considered. I do not think it is foolish to assert that an intensive comparative anthropological research, backed by a judicious use of experiment, could begin to predict with greater accuracy the timing of social change.

More: we know now that, with selected groups, it is possible to use methods to accelerate the establishment of the new and the discarding of the old. Why should the social anthropologist not look, in his field observations, for the ways in which these methods work in the unselected social community? It is not impossible.

Most people believe, and it is probably true, that the quickening of the means of communication and the enhanced control of natural resources which modern science has made possible have greatly accelerated the rate of change brought about by culture contact. It is an unevenly distributed acceleration, much more apparent in the fields of material culture than elsewhere. It may produce a false and a dangerous optimism—indeed, I think it has already done this—which may work havoc in the post-war world, unless the timing of the changes which one community can introduce into another is studied as scientifically as are the most favourable points of entry of such innovations.

One further consideration. It is not uncommon to find some feature of encroaching culture, coming from outside, apparently received into a group, and even given an enthusiastic welcome; but within a short time it has lost its place. Either it has gone as if it had never been, or it has changed into a form so identified with some pre-existing group of elements that it has lost all its integrity. Finding points of favourable entry is necessary, but it is not the same thing as discovering means of ensuring permanence. This is a task possible only for the anthropological team working in the field. I must confess that my field anthropological experience is lamentably slight, and it is with apologies that I use a case which came within my own attention.

However, I did once arrive at a fairly remote African group at a time of minor crisis. Certain practices, popularly denominated "witchcraft", had just been, for admirable reasons, blankly and with penalties prohibited. They were 'hard' points of culture and the chief effect was to drive them underground. When I arrived certain men, called "witch-doctors" by all the European inhabitants, were suffering periods of enforced inactivity. Naturally I looked them up, and it seemed clear that one or two at least were men of superior intelligence and alertness of mind. As soon as good relations were established they talked freely, and although I was in the unsatisfactory position of having to use an interpreter, one thing impressed itself on me at the time. I tried as simply as possible to explain a little about our own practice of psychological medicine. Perhaps it was only my fancy, but I thought I was met by a quickness and sympathy of understanding and an interest not by any means very common yet in the European world.

I think, if the possibilities of this had been more fully realized, the situation might have been better handled by the representatives of the European culture, but I had no chance to experiment and so far as I know nobody has tried this experiment since. I have, however, often looked for cases in which cultural change induced by contact has endured and at the same time maintained a certain integrity.

It does seem to me possible to collect a few general suggestions which may be used to guide the necessary further field research. If some detail is detached from one social setting and passes into another, it is exceedingly unlikely that it will survive for long in its original form. The most likely thing, if it persists at all, is for it to appear as a detail integral to the receptive culture. There are cases of endurance in such circumstances but, though I cannot claim wide knowledge, I know of none in which the detail exchanged acquires any functional importance in its new setting.

If items that are transferred are to endure in approximately their original form and function, they must be given a concrete expression—something that can be seen, or heard, or performed; and this is the more important the more unselected and diverse is their new social group. There appears to be an intimate relation between certain types of expression and certain classes of item, and I think that to clear up and formulate these should be a primary object of field study.

The permanence or transitoriness of changes induced by the contact of cultures is closely dependent upon the link between these changes and other material in both the transmitting and the receiving groups. In other words, there is much truth in the view that culture moves in blocks. But very little is known about either the nature of the links required or about how they work. Nothing but directed research in the field can make these clear.

Finally, I suspect very strongly that no group can influence another permanently, except by establishing very friendly working relationships with a group which already possesses some social prestige within the receptive community, and the prestige of which will manifestly increase if it accepts and gets, to begin with, something like a 'corner' in the incoming reforms.

How do I picture an anthropology with a wider understanding and a greater potential power of guidance of the destinies of man? Certainly I do not see anthropologists as administrators, or administrators as anthropologists. The basic need is for the further development of anthropological research and teaching. If these grow as I see them, they will themselves constitute a co-operative effort in which many interests will combine. Perhaps in this way the immediate future of anthropology may become a mirror of the future of the wider world of mankind.

BLOOD PIGMENTS AND RELATED SUBSTANCES

A MEETING of the Biochemical Society held on November 13 was devoted to papers and discussion on "The Tetrapyrrolic Pigments".

Prof. D. Keilin gave an introductory survey of the properties and functions of natural tetrapyrrolic pigments. The iron derivatives of porphyrins, or hæmatins, form the active or prosthetic groups of many biologically important substances: hæmoglobins, cytochromes, catalase and peroxidase, which play fundamental parts in oxygen transport and cellular oxidations. The iron atom of hæmatin lies within the flat tetrapyrrolic ring system united by four covalencies to the pyrrol nitrogen atoms, while the remaining two valencies lie above and below the ring.

The porphyrins are highly fluorescent in ultraviolet light and show sharp absorption spectra. Although they combine with many metals, only the iron derivatives combine with proteins forming intracellular catalysts. The proteins are not colloidal carriers but integral parts of the molecule, and various proteins can combine with the same hæmatin to give catalysts of widely differing properties. The sharp absorption spectra of intracellular hæmatin compounds, particularly of the cytochromes, make possible the detailed study of cellular respiration by spectroscopic examination. All aerobic cells can synthesize the porphyrin nucleus and build up specific hæmatin catalysts. Anaerobic bacteria are devoid of hæmatin. A few exceptions to this rule are aerobes normally living in presence of hæmoglobin, for example, *Hæmophilus influenza* and *H. canis*. Cultures of these organisms need the addition of protohæmatin or protoporphyrin as a growth-factor.

The work of Pauling and Coryell on the iron-porphyrin linkage divides hæmatin derivatives into two groups; in one the linkages are covalent and in the other mainly ionic. Oxyhæmoglobin belongs to the former and hæmoglobin to the latter—an unexpected result which can only be explained by a fundamental electronic re-arrangement within the oxygen molecule when it combines with hæmoglobin.

The facile oxidative degradation of hæmatin *in vivo* to bile pigments, involving the opening of the porphyrin ring to a straight-chain tetrapyrrol, is in strange contrast to the great stability of porphyrins over millions of years in bituminous oils and coproliths.

Prof. H. Munro Fox dealt with the varieties of hæmoglobin. All hæmoglobins contain the same hæmatin nucleus, but the globin varies with the species and even within the species. Hæmoglobins of some invertebrates (erythrocruorins) differ from those of vertebrates in that they show high molecular weight, low iso-electric point and markedly different amino-acid analysis. Hæmoglobins of animals differ in many ways; for example, in spectra and in oxygen affinity. In the case of rabbits, spectrum differences have been observed among individuals. These differences must depend upon variations in globin structure, as also must the antigenic properties. Sir Joseph Barcroft's work on fœtal respiration has demonstrated the vital higher oxygen affinity of fœtal over maternal hæmoglobin.

The role of hæmoglobin in invertebrates seems less vital. Not only is its occurrence rare and very spasmodic, but also some species such as Chironomus can survive gassing with carbon monoxide. The respiration of this worm is only affected by carbon monoxide at very low oxygen pressures, when presumably the hæmoglobin comes into play as a carrier. A remarkable case of hæmoglobin increase in response to oxygen deficiency is that of Daphnia, which will change in a few days from bright pink when oxygen is deficient to colourless in well-aerated water, and vice versa.

The question of the formation and maintenance of hæmoglobin in invertebrates came up for discussion. In vertebrates the bone marrow controls hæmopoiesis, and the hæmoglobin is maintained in the ferrous state by specific intracorpuscular reactions. It is difficult to propose any corresponding mechanisms in invertebrates.

The function of tetrapyrrolic pigments in plants was reviewed by Dr. R. Hill. The fluorescence of porphyrins is decreased on combination with metals except in the case of the magnesium derivatives, and it is therefore understandable that chlorophylls, as photosynthetic agents, are magnesium porphyrin compounds.

Besides chlorophylls *a* and *b* in the ratio 3 : 1, a third derivative, protochlorophyll, with two hydrogens less in the porphyrin ring, may occur in higher plants. A fourth member of this class, chlorofucin, occurs in diatoms and brown algæ. The red, blue and green algæ all contain chlorophyll *a* together with varying amounts of two fluorescent bile-pigment protein complexes, phycoerythrin and phycocyan. Many algæ show the property of chromo-adaptation and, when grown under coloured light, may assume the complementary colour.

The respiration of plants is catalysed by the same types of tetrapyrrolic compounds as are present in animal tissues. A plant extract has been obtained which shows the same cytochrome spectrum as that of baker's yeast or washed muscle tissue and will oxidize *p*-phenylenediamine and succinate. The oxidation and reduction of cytochromes can be observed spectroscopically in plant tissues. Two other specifically plant cytochromes have been isolated but their function has not been established.

In subsequent discussions Prof. Keilin described experiments proving that the cytochrome oxidase system and not the polyphenol oxidase is responsible for the bulk of plant respiration. The evidence was based on the effect of carbon monoxide on respiration. With the former enzyme the effect of carbon monoxide is sensitive to light; with the latter it is not.

The problem of the constitution of catalase was considered by Dr. E. F. Hartree in two ways: its close analogy with methæmoglobin, and the significance of the bile pigment derivatives normally found in the highly purified enzyme. The close analogy of methæmoglobin with peroxidase and catalase is apparent from colour and absorption spectra, and also from reactions with respiratory inhibitors such as cyanide, azide and sulphide. The spectrum changes obtained on addition of these inhibitors, and also of hydrogen peroxide and organic peroxides, show that atalase contains hæmatin, with trivalent iron, combined with a specific protein.

The isolation of biliverdin from catalase on treatment with acid acetone, together with a study of the hæmochromogens obtained from catalase after the addition of pyridine, indicate the presence of a bile pigment–iron–protein complex in catalases which appear homogeneous by physical criteria. Although it was at first accepted that the catalase molecule ontains one bile pigment grouping and three hæmains, it was later proved that the bile pigment plays no part in the activity of the enzyme and is not herefore built into the molecule during synthesis. The bulk of the evidence suggests that the bile pigment groups are the result of oxidative degradation of catalase hæmatins during normal metabolism, and are not formed during the processes of extraction and analysis of the enzyme preparations.

The findings of Keilin and Hartree on the ability f catalase to promote an oxidation of certain substances by the 'active' hydrogen peroxide formed during certain enzymic oxidations were brought forward to support a theory of catalase degradation *in vivo*. It was suggested that such a coupled oxidaion of catalase occurs in the liver, which produces hydrogen peroxide during certain oxidation reactions. n this way the facile oxidation of catalase in the liver can be reconciled with its resistance to degradation by treatment with high concentrations of ydrogen peroxide. This question of an active or nascent form of hydrogen peroxide was taken up in the ensuing discussion, when an example of a similarly active form from an inorganic source (decomposition of barium peroxide) was cited.

Dr. J. R. P. O'Brien's paper reviewed the present state of our knowledge of the hæmoglobin molecule based on physico-chemical and X-ray measurements, and the synthesis and breakdown of hæmoglobin; processes dependent on the activity of the bone marrow and the liver.

The theory that globin is attached to iron via iminazol groups finds support in *p*K measurements of iminazols, but there is no evidence that the iminazol ring of histidine is involved. Histidine is found in all hæm proteins, consequently the unique globin-hæm linkage conferring the property of oxygenation is more likely to depend upon some group peculiar to globin. In this connexion it must be borne in mind that less than 70 per cent of the globin molecule has been accounted for by amino-acid analysis.

Porphyrin production can be maintained under adverse conditions, though the iron and globin supplies for hæmoglobin synthesis depend largely on dietary supply. The mode of synthesis of hæmoglobin is unknown, though further knowledge of the structure of the molecule as, for example, is available from the X-ray measurements of Perutz, may shed light on this problem. The first stage in hæmoglobin catabolism appears to be the 'easily splittable iron' of Barkan, which accounts for about 5 per cent of erythrocytic iron. The process then passes via biliverdin and bilirubin to urobilin. The latter is partly excreted as such and partly after further breakdown to pyrromethines.

The beneficial effect of ascorbic acid in T.N.T. methæmoglobinuria indicates the necessity for a reducing agent within the erythrocyte to maintain hæmoglobin in the ferrous state. This mechanism may be intimately connected with glucose metabolism.

In the discussion that followed, the absence of the Soret, or γ, band in the absorption spectrum of red-cell suspensions was considered. Prof. Keilin brought forward evidence that this is a purely optical phenomenon and cannot be accounted for by the theory of a hæmoglobin-stromatin complex. Thus the band is absent from a suspension of hæmoglobin droplets in oil.

Dr. C. Rimington dealt in detail with the pathological conditions in which large quantities of uro- and coproporphyrins are formed and excreted. Free porphyrins occur normally in small quantities in plants, bacteria, yeasts, and many animal tissues. Protoporphyrin does not appear in pathological conditions, while the uro- and coproporphyrins each appear in two isomeric forms (Series I and III of Fischer). It is not possible to regard one as normal and one as pathological. While the coproporphyrins are normal constituents of urine and fæces, the presence of uroporphyrins must be regarded as pathological, although certain squirrels excrete large quantities. The most striking instance of uroporphyrin production is in the *turacos*; these African birds have wing feathers coloured bright red by copper-uroporphyrin III.

The porphyrinopathies may be divided into three groups: (1) *Porphyrinuria* may be brought about in any person by certain factors; for example, hepatic dysfunction, lead or sulphonal poisoning. Urinary coproporphyrin is greatly increased. (2) *Porphyria congenita* is a rare condition present from birth and probably hereditary. Copro- and uroporphyrins are excreted in large quantities in the urine and fæces, and the teeth and bones are brown. The photoactive porphyrins produce considerable photosensitization. A similar disease is known in cattle. (3) *Porphyria acuta* appears later in life. There is no bone pigmentation or photosensitivity, but much porphyrin is excreted during attacks. Other sets of symptoms may predominate and the disease is usually fatal.

Porphyrins are to be regarded as products of deranged hæmoglobin synthesis rather than as degradation products. Further knowledge of hæmoglobin synthesis will no doubt help to elucidate the problems of the abnormal production of porphyrins.

This meeting was very successful, but could have been improved by the allotment of more time for discussion of the many interesting points raised by each contributor. Sir Joseph Barcroft, in his concluding remarks, expressed the hope that the proceedings would be published *in extenso* to allow a more careful study of a valuable contribution to our knowledge of the tetrapyrrolic pigments.

OBITUARY

Dr. W. H. Hatfield, F.R.S.

Dr. William Herbert Hatfield, director of the Brown-Firth Research Laboratories, Sheffield, who died on October 16 after a very short illness, had played a leading part in the development of metallurgical research in Great Britain, besides holding an important position in the steel industry. He was born in Sheffield on April 10, 1882, and worked in the laboratory of Messrs. Henry Bessemer and Co., studying at the same time at University College, Sheffield, under Prof. J. O. Arnold.

Hatfield went to the firm of J. Crowley and Co. as metallurgist, and while there published his first original research, a study with Prof. A. McWilliam of the elimination of silicon in the acid open-hearth. A second joint paper on the same subject followed in 1904. He was awarded the Mappin Medal and also a Carnegie Scholarship, which led to the publication in 1906 of a memoir on the forms of carbon in cast iron. In 1909 he developed this subject further, and showed that, contrary to the widely accepted statements of Wüst, it was not necessary that carbon should be precipitated as temper graphite before being oxidized in the production of malleable castings. The experiments, which were well designed to settle the point, were conducted in the works, the microscopical studies being made in Prof. Arnold's department, now a faculty of the University. These investigations were next expanded into a book.

In 1916 Hatfield succeeded Mr. Harry Brearley as director of the Brown-Firth Laboratories, and gathered round him a technical staff. Brearley had in 1912 invented the first 'stainless' steel, a high-chromium steel which when correctly heat-treated was highly resistant to corrosion, and found special application in cutlery. To administer the patent rights the Firth-Brearley Syndicate was formed. In the meantime, Messrs. Krupp of Essen had covered by patents a wide range of steels containing both nickel and chromium, with the primary object of using them for high temperatures, although their resistance to corrosion at atmospheric temperatures had also been noted. Hatfield made a thorough study of these steels, and selected 18 per cent chromium and 8 per cent nickel as giving the most useful results when suitably made and treated. This "18 : 8", to which Firths gave the name of 'Staybrite', became the most widely used of this series of alloys, and its success was largely due to the energetic efforts of Hatfield. He made a detailed study of the properties of the austenitic stainless steels, especially of the intercrystalline corrosion to which they were liable under certain conditions, as when welded. This difficulty was overcome partly by keeping the carbon content low and partly by adding carbide-forming elements, such as titanium. The activities of his own firm, of which he became a director, led him to give much attention to steels for guns, aircraft and marine forgings, and his later researches dealt mainly with alloy steels, especially with mechanical properties, behaviour at high temperatures, resistance to creep, and corrosion.

As a result of experiences in the War of 1914–18, certain research committees were set up by the Iron and Steel Institute, but after the first enthusiasm had passed there was a danger that their ambitious programmes might be dropped, and it was owing to Hatfield that a definite scheme was put in hand in 1924 with the object of determining the nature and causes of heterogeneity in steel ingots. This Ingots Committee, of which he was chairman, was followed by similar committees on corrosion, alloy steels, and steel castings. These and other committees and sub-committees were co-ordinated under the Iron and Steel Industrial Research Council. There is no doubt that this organization, which has been and still is responsible for co-operative research in the steel industry of Great Britain on a large scale, owes its success very largely to Hatfield, who had the art of persuading manufacturers to co-operate by pooling information, contributing money and materials, and undertaking experiments in their works, while universities and public institutions such as the National Physical Laboratory were effectively brought into the scheme.

The present War brought Hatfield new and heavy tasks. As chairman of the Technical Advisory Committee on Alloy Steels, he was instrumental in reducing to a small number the great mass of steel specifications, thus simplifying the work of the steel maker and economizing the rarer metals. In the summer of the present year he was a member of an iron and steel mission to the United States, which he had visited once before in 1928, when he gave a series of lectures afterwards published in book form. The extra strain no doubt told on him, and although his health had seemed invulnerable, the end came rapidly.

Hatfield enjoyed controversy, and in committees could be deliberately provocative, but it was possible to differ strongly from him either on scientific matters or on questions of policy without any break of personal friendship, for he was incapable of bearing malice, and differences were soon healed. Sheffield, where most of the research committees usually met,—will seem a different place without him, and he will be equally missed at the meetings of many technical societies. In 1907 he married Miss Edith Marian Seagrave, and he owed much during the stress of scientific and commercial work to the companionship and support of his wife.

Dr. Hatfield was elected a fellow of the Royal Society in 1935. He received the Bessemer Medal of the Iron and Steel Institute, of which he was a devoted member, in 1933, and became a vice-president in the following year. He founded the Sheffield Metallurgical Association, of which he was the first president, and held office in many other societies.

C. H. Desch.

NEWS and VIEWS

Foundation for Educational Research

THE Foundation for Educational Research, recently set up in association with the University of London Institute of Education, owes its origin to an offer of 10,000 dollars from the Carnegie Corporation of New York. This was made to encourage a 'carry-over' of interest in research from the work done under the directorship of Sir Philip Hartog by the English Committee of the Carnegie International Examinations Enquiry. The conditions attached to the offer were that the money would be paid over as equal amounts were subscribed in England, and that the fund should be administered by the Institute of Education. A generous grant of £1,000 from the Leverhulme Trustees thus made the sum of £2,000 available. As soon as conditions permitted, the Institute constituted an advisory council, and this body urged a considerable expansion of the original scheme so as to provide for a period of at least five years of systematic work. This expansion is now being put into effect with good hopes of wide support. The intention is that the present organization shall merge itself into a permanent national organization as soon as that stage can be reached. The first piece of work to be undertaken is a programme of researches designed to arrive at trustworthy diagnostic techniques for the 'sorting' of the young adolescent population which will be necessary in carrying into effect the White Paper proposals for post-primary education in Great Britain.

University Grants Committee

THE Chancellor of the Exchequer has announced that the membership of the University Grants Committee has been increased from ten to fifteen. It is constituted as follows: Sir Walter Moberley (chairman), formerly vice-chancellor of the University of Manchester; Dr. E. A. Benians, Master of St. John's College, Cambridge; Prof. W. E. Collinson, professor of German in the University of Liverpool; Sir Charles Darwin, director of the National Physical Laboratory; Miss Margery Fry, formerly principal of Somerville College, Oxford; Sir Robert Greig, director of the London, Midland and Scottish Railway, member of the Carnegie Trust for the Universities of Scotland and of the Agricultural Research Council; Prof. A. V. Hill, Foulerton research professor of the Royal Society; Dr. P. D. Innes, chief education officer, Birmingham; Sir Frederic Kenyon, formerly director and principal librarian of the British Museum; Prof. P. S. Noble, regius professor of humanity, University of Aberdeen; Principal Andrew Robertson, recently professor of mechanical engineering, University of Bristol; Prof. E. J. Salisbury, director of the Royal Botanic Gardens, Kew; Dr. J. C. Spence, lecturer on diseases of children, University of Durham; Prof. R. H. Tawney, professor of economic history, University of London; Sir Henry Tizard, president of Magdalen College, Oxford.

University of Oslo

AT the seventh meeting of the Conference of Ministers of Education of the Allied Governments, held in London at the offices of the Board of Education on December 7, with Mr. R. A. Butler, M.P., in the chair, the following message of sympathy and encouragement, with which the Conference associated itself, was handed to the Norwegian Minister of Education:

"We in Great Britain have been deeply shocked to hear of the brutal action by the German Occupying Power in Norway against the students and teaching staff of Oslo University. We are well aware that the arrest and threatened deportation of the flower of Norway's youth are designed to crush Norwegian intellectual resistance and to strike at those reserves of trained minds, which will be so badly needed during the post-war reconstruction period. We have watched with pride and admiration the unarmed struggle of your Nation. We have seen how your people have used the rich resources of their cultural and educational tradition, which we so greatly respect, to resist every attack by their oppressors. Norway's intellectuals have stood firm against trickery and enticement, against brutality and reprisals. All those concerned with education in Britain will join in sending our sympathy to our colleagues in Norway and particularly to Norwegian students and teachers. We know that this latest attack will be as fruitless as any other of the Nazis' efforts to subjugate the Norwegian people. We are confident that it will recoil inexorably on the heads of its instigators. Once more the Nazis have shown their determination to suppress every vestige of freedom of thought. The example of the Oslo students and teachers will strengthen the resolution of all defenders of liberty throughout the world."

Council for the Promotion of Field Studies

As a result of a preliminary investigation carried out by Mr. F. H. C. Butler, a meeting convened by him was held on December 10 at the British Museum (Natural History) to inaugurate a Council for the Promotion of Field Studies. Attending this meeting were some thirty-five delegates appointed by universities of England and Wales, university colleges, scientific societies and institutions, including the National Trust and the Council for the Preservation of Rural England. Prof. F. E. Fritsch was in the chair. Mr. Butler made a general statement of the aims of the proposed Council. He had found, he said, very strong support for his view that the facilities for study and research in the field needed to be much improved; one of the main functions of the Council would be to establish and maintain hostels for field studies, under trained wardens, in various parts of the country. It seemed to be widely felt that the Council could fill a very important gap in our system of education both at the school and university level. His address was followed by a full and interesting discussion; the motion to form the Council was then put to the meeting and carried unanimously. The following were appointed as officers and members of the executive committee: Mr. F. H. C. Butler, Primrose Farm, Little Wilbraham, Cambridge, honorary secretary; Mr. C. C. Fagg, honorary treasurer; Prof. F. W. R. Brambell, Mr. M. C. Burkitt, Dr. A. R. Clapham, Dr. H. Godwin, Prof. W. T. Gordon, Mr. L. A. Harvey, Mr. O. D. Kendall, Mr. N. B. Kinnear, Prof. W. B. R. King, Mr. R. H. Kinvig, Prof. W. H. Pearsall, Mr. H. J. F. Smith, Prof. A. G. Tansley, Mr. R. R. Tomlinson, Prof. C. W. Wardlaw, Prof. C. M. Yonge. The Board of Education will be represented by Mr. F. H. B. Fox and the Scottish Education Department by Mr. J. W. Parker, who will act in an advisory capacity.

Controller-General of the Ministry of Fuel and Power: Dr. H. S. Houldsworth, K.C.

DR. H. S. HOULDSWORTH, K.C., who from January 1, 1944, becomes controller-general of the Ministry of Fuel and Power, graduated in science at the University of Leeds in 1911, taking first-class honours in physics as a student of the late Sir William Bragg. After some years of school-teaching and after the outbreak of war, he entered the Fuel Department of the University on the staff of Prof. J. W. Cobb, the regional deputy inspector of high explosives, visiting works for the sampling and testing of their products. In 1918 with the coming of peace he remained with Prof. Cobb in a newly created post as research assistant on refractory materials, working, and later lecturing, on that subject. In a period of seven years he was joint (or sole) author of a series of papers, mainly for the Ceramic Society, dealing with such matters as the thermal expansion of refractories and the transformations of silica, and although he entered on this work with no special knowledge of the subject, then little studied, he grappled with it effectively and in 1925 was awarded the D.Sc.

Meanwhile Dr. Houldsworth retained and developed an interest in public work in close association with Sir John (now Lord) Simon, the member of Parliament for Spen Valley, and with his encouragement read successfully for the Bar examinations and entered on a new career as barrister. Here he had no long waiting period, but was soon busy, particularly with the coal industry and its multitude of agreements and discussions of one kind and another, in which owners, miners, users and Government authorities were involved. His variety of experience with people differing so widely in training, position and outlook, combined with innate qualities to make him increasingly valued both for sanity of judgment and honesty of purpose. The same qualities have no doubt marked his tenure of office as regional controller of the Ministry of Fuel and Power for the North Eastern Division, to which he was called when the war effort for fuel economy came under Government organization. The extension of his responsibilities now announced will be widely welcomed, particularly by those who have known his work. Typical of his methods was the Yorkshire Fuel Efficiency Committee, for which he secured the effective collaboration of industrial, academic and official representatives and the willing assistance of trained men, in the drive for economy in the industrial uses of fuel.

Government Fuel Research in Great Britain

IN an address to the Institute of Fuel in Newcastle upon Tyne on December 13, Dr. A. Parker, director of fuel research of the Department of Scientific and Industrial Research, surveyed the activities of the Fuel Research Board. To-day, this State organization, with a staff of more than 250, includes the central Fuel Research Station, equipped not only for experiments in the laboratory, but also for experiments on a semi-commercial scale and on a full commercial scale. The full-scale units include plants for cleaning, drying and pulverizing coal, for the manufacture of fuel gases, hydrogen and coke, and there are full-size boilers of several kinds. Experimental work has also been undertaken in co-operation with industry. In addition to the Fuel Research Station, there are nine coal survey laboratories in various parts of England, Scotland and Wales which have been undertaking, in collaboration with the Geological Survey, a comprehensive survey of the qualities of the coal resources of Great Britain. This survey is now being put on a quantitative basis in co-operation with the Coal Commission and the Ministry of Fuel and Power. As a result of this survey, we already have much more information about our coal reserves and the coals on the market than there is about the coals in any other country. Referring to achievements of the fuel research organization, Dr. Parker stated that simple equipment has been developed for fitting to large industrial boilers, which not only greatly reduces the quantity of smoke from the boiler chimney but also increases the efficiency of the coal in raising steam, and work on transport producers using coal and coke in place of petrol for road vehicles, begun at the Fuel Research Station before the War, has led to the introduction of the Government Emergency Producer now in use on many road vehicles. Processes for the production of petrol and other oils and chemicals from coal have received considerable attention at the Fuel Research Station, and a great deal of information has been obtained from experimental work on the distillation of coal, hydrogenation of coal and of tar, and on synthetic methods of producing oils and chemicals from gases made from coal and coke.

Continuing, Dr. Parker said that if Great Britain is to maintain its position in industry, we must rapidly develop our scientific and industrial research in relation to coal and other fuels, in the widest national interest. There must also be a spirit of mutual help in research, involving friendly discussion and collaboration between the scientific men in universities, in Government establishments, industrial research associations, and other research organizations. In relation to fuel in Great Britain, a good beginning in this direction has already been made. The Department has set up a consultative conference on fuel research, which is attended by representatives of the Iron and Steel Industrial Research Council, the British Refractories Research Association, the British Electrical and Allied Industries Research Association, the British Coal Utilization Research Association, the British Hard Coke Research Association, and the Gas Research Board. In his concluding remarks, Dr. Parker issued a note of warning. He said that where there is a lack of the real appreciation of the conditions under which successful research is carried out, there is an impression that if large sums of money are provided for research, marvellous discoveries would follow as a matter of course. While adequate financial provision is naturally essential, it is not in itself enough. The primary requirement is men of the right training and outlook.

Commemoration of the Invention of the Barometer

AT the University of Toronto on October 19, two meetings were held to commemorate the invention of the barometer by Torricelli, three hundred years ago. Last spring, the Canadian Branch of the Royal Meteorological Society decided that this important scientific event should be fittingly commemorated, and invited the Royal Astronomical Society of Canada, the Royal Canadian Institute, and the University of Toronto to join with it in making the arrangements, which were entrusted to a committee under the chairmanship of Mr. W. E. K. Middleton. At the afternoon meeting held in the West Hall of the University College, Prof. C. A. Chant was chairman, and presented to the meeting delegates from the Royal Society of Canada, the American Meteorological Society and the History of Science Society. The first formal paper, entitled "Telescope, Microscope, and Barometer as a Point of Departure for the Natural Sciences", was delivered by Prof. Louis C. Karpinski, of the University of Michigan, president of the History of Science Society, who treated the discovery of the barometer as one phase, and an important one, of the scientific renaissance that took place in the sixteenth century. He was followed by Prof. G. S. Brett, of the University of Toronto, who dealt with the remarkable effect of the discovery on contemporary thought, particularly as it affected the relations between science and theology, and the ideas of the structure and properties of matter.

The evening meeting was held in the McLennan Laboratory of the University of Toronto, under the chairmanship of Dr. J. Patterson, controller of the Canadian Meteorological Service, who opened the proceedings by repeating the Toricellian experiment before a large audience. Mr. W. E. K. Middleton, of the Meteorological Office, then gave an illustrated lecture on the subsequent history of the barometer, showing many slides of interesting instruments developed throughout the past three hundred years. Finally, Prof. John Satterly, of the University of Toronto, presented a paper on the applications of the barometer in physics and chemistry, and emphasized the need for considerable precision when the barometer is used in physical research. It is hoped to publish these papers in the *Journal of the Royal Astronomical Society of Canada*.

The Chinese Medical Journal

The reappearance of the *Chinese Medical Journal*, the publication of which, says the *Lancet* (559, Oct. 30, 1943), was suspended by the occupation by the Japanese of the Chinese Medical Association's offices, coincides with the publication of a book by one of the editors of the *Journal*, Dr. Szeming Sze, entitled "China's Health Problems". Dr. Sze, who was educated at an English public school, at the University of Cambridge and at St. Thomas's Hospital, is also general secretary of the Chinese Medical Association, which now has offices at Washington, the address of which is P.O. 6096. Reviewing Dr. Sze's book, the *British Medical Journal* (580, Nov. 6, 1943) indicates the magnitude of China's health problems. The morbidity-rate is 4 per cent of the population, which means that, in any one day, about 16 million people are ill in China. To treat these there are, in the whole country, 12,000 doctors and 38,000 hospital beds. The usual medical standards require that there should be at least 266,000 doctors and 2 million hospital beds. As things are, many Chinese people still rely exclusively on native methods of treatment. Anyone who is interested in one aspect of these should read the article on Chinese Anthelmintic Prescriptions from the Han period (about 217 A.D.) to the present time (1940) by C. S. Chao, in the *Chinese Medical Journal* (57, 251–289; 1940).

It is proposed to publish the *Chinese Medical Journal* quarterly from the United States until the end of the War, and at the same time to issue from Chungking a medical digest in the Chinese language. The other editor of the *Journal* is Dr. J. Heng Liu. The first issue of the newly published *Journal* includes accounts of typhus fever in Kunming and Shanghai, and articles on malaria, cholera and plague. The work of the Weishengshu Anti-epidemic Corps, which sends mobile units from Chungking all over free China, is described. It is stated that Japanese aeroplanes dropped parcels of grain and rags, containing plague-infected fleas, over Changteh in November 1941; a few days later bubonic plague broke out in the city. News is also given of various agencies and relief organizations now at work in China. The Henry Lester Institute at Shanghai is still active, but its director is now Japanese. The Peking Union Medical College and Hospital are, however, closed and their director, Dr. H. S. Houghton, has been interned.

Train Orders by Facsimile Telegraphy

Facsimile telegraphy is one of the devices recently called upon by the railways to help meet the unprecedented demands of to-day. It has many advantages over other forms of communication for several railway applications. For example, its inherent accuracy makes it an ideal method for the handling of train orders and once the order is prepared for transmission it need never again be copied manually. The possibility of transmission error is greatly reduced by the fact that the method can operate through extremely high levels of interference. Simplicity of operation and the ease with which duplicate copies may be secured are additional advantages. Automatic recorders, housed in small shacks along the right-of-way, are located at sidings, branches, crossings—wherever a train might be required to stop. Recorders may also be installed in small stations where telegraph service is not provided. An automatic transmitter, under control of the operator for the district, is arranged so that he may transmit orders to any of these recorders.

Since the recorders are entirely automatic, the order may be transmitted in advance of the arrival of the train. The circuit is arranged so that the transmitter may be set by the operator to send automatically as many copies of the order as are required by the various members of the train crew, and the orders are thus secured with a minimum of time and effort. The time and effort required of the operator are equally slight; he dials the desired recorder, sets an indicator to the desired number of copies, and drops the order into the machine. The messages simply roll out of the machine into a receptacle whether or not there is anyone present to receive them. A recorder readily adapted to such service was developed by the Western Union Telegraph Company for use in conjunction with automatic transmitters, and the equipment comprises what is probably the most completely automatic telegraph system yet devised. An article by J. H. Hackenberg (*Elec. Comm.*, 21, No. 2; 1943) describes and illustrates the new equipment and its mode of operation.

A South American Review of Newton's Work

In a paper entitled "El Tricentenario De Newton", Mario Bunge examines five different aspects of Newton's work (Buenos Aires: Universidad Obrera Argentina Instituto Cientifico, Seminario De Filosofia, November 1942. Pp. 8). The first of these is his discovery and application of the infinitesimal calculus, a discovery which unfortunately caused some unpleasant feeling with Leibniz, though, as is pointed out, each represented a distinct school so that their contributions can be regarded as complementary.

Secondly, Newton was responsible for the introduction of the deductive method in the natural sciences and so rendered signal service to mankind as the founder of mathematical physics, which has been the basis of so much in science for two and a half centuries. Then, his rational mechanics had a profound influence for many generations. Newton's differential equations showed how the state of the universe today is the result of all its past history, and its future history could be determined by its present. This required a strict determinism which obsessed the minds of men of science for a long period, though in comparatively recent times there has been a strong reaction against it. His work on optics showed his ability as an experimental physicist. Newton's subordination of optics to mechanics, far from enhancing progress, was a principal cause of the lack of progress in optics during the eighteenth century. An ironical result of his experiments with diffraction and interference was the death-knell a century later of his corpuscular theory of light. Lastly, Newton's philosophical work must not be forgotten. Space and time were objective and independent of our perception of them, according to Newton, and were not *a priori* representations which served for the foundations of all external intuitions. Force, energy, mass, motion, as well as space and time, were all objective entities for Newton. His work must be considered a model of the systematic application of scientific method—a model of the power of reason to investigate the natural, controlling and ruling it, by placing it at the service of progress, material, cultural and moral, of humanity.

Earthquakes Recorded during September

THE U.S. Coast and Geodetic Survey has determined the epicentres of six earthquakes occurring between Sept. 5 and 20. The first was on Sept. 5 from lat. 0° long. 125° E., which is in the Molucca Passage east of the island of Celebes in the East Indies; time at origin, 8h. 34·8m. The second was on Sept. 6 from an epicentre lat. 53·2° S. long. 159·4° E., which is north-east of the Macquarie Islands, south-west of New Zealand; time at origin, 3h. 41·5m. The third was on Sept. 10 from an epicentre lat. 18·9° N. long. 67° W., which is near the north-west coast of Porto Rico in the West Indies, time at origin being 2h. 31·6m. The fourth was also on Sept. 10, from an epicentre near lat. 35·1° N. long. 133·3° E., which is in the Pacific Ocean west of California, time at origin being 8h. 36·9m. The fifth was on Sept. 11, from an epicentre near lat. 16½° S. long. 173° W., which is in the Pacific Ocean between Samoa and the Friendly Islands and east of Fiji. Time at origin was 19h. 34m. The sixth was on Sept. 20 from an epicentre near lat. 19½° N. long. 109° W., which is in the Pacific Ocean west of Mexico and north-east of Revilla Gigedo Island. Time at origin was 00h. 53·7m.

Earthquakes were registered at Kew on Sept. 5 at 08h. 49m. 11s. from an epicentre 12,000 km. distant; on Sept. 6 at 04h. 01m. 32s. from an epicentre 18,700 km. distant (maximum amplitude at Kew 440 μ); and on Sept. 10 at 08h. 49m. 32s. from an epicentre 9,560 km. distant (maximum amplitude 250 μ at Kew). All times are in Universal Time and interpretations and calculations are provisional.

On October 26 an earthquake was felt in San Francisco. Some telephones were put out of action, some windows broken and some articles jolted off shelves.

Announcements

THE title of professor of technical optics in the University of London has been conferred on Dr. L. C. Martin in respect of the post held by him at the Imperial College of Science and Technology.

THE University of Oxford has accepted an offer from the Lord Nuffield Provincial Hospitals Trust of £8,000 a year for research in plastic surgery and for training in that branch of surgery.

DURING 1943 the Royal Society of South Africa elected the following fellows: John G. Rose, formerly Government analyst and chief chemist to the S.A. Railways and Harbours, Cape Town, for his valuable applications of chemistry in the field of engineering; and Hillel A. Shapiro, assistant Government pathologist, Cape Town, for his work on experimental physiology and malnutrition. The Abbé Henri E. P. Breuil, the distinguished archæologist, at present attached to the University of the Witwatersrand, Johannesburg, has been elected an honorary fellow of the Society.

THE Charles L. Mayer Award for 1943 will be made by the National Science Fund of the U.S. National Academy of Sciences for an outstanding contribution to present-day knowledge of factors affecting the growth of animal cells, with particular reference to human cancer. In addition, the advisory committee requests recommendations from scientific men of persons whose present work is in this field and who are achieving outstanding results. The closing date for the receipt of manuscripts and published articles is January 15, 1944; they should be sent to the National Science Fund of the National Academy of Sciences, 515 Madison Avenue, New York 22, N.Y.

MESSRS. H. K. LEWIS AND CO., LTD., 136 Gower Street, London, W.C.1, have issued a price list of certain German publications which are being reproduced in the United States by photo-offset process under authorization of the Alien Property Custodian in Washington. It includes books on mathematics, physics and chemistry, mainly published during the period 1930–40; among the titles are many standard works of references, as well as recent technical books. Messrs. Lewis are accepting orders, but anticipate a delay of three months in obtaining copies.

SIX popular lectures on astronomy have been arranged by the Royal Astronomical Society and the British Astronomical Association, and are being given on Fridays at the Royal Astronomical Society's rooms in Burlington House, Piccadilly, London, W.1, for members of the British and Allied Forces. The first was given on December 3 by Sir James Jeans on "Photographic Astronomy". On December 17 Prof. W. M. Smart is speaking on "The Origin of the Earth". Succeeding lectures will be given on January 7, by Mr. B. M. Peek, on "The Planets and Planetary Observations"; on January 21, by Prof. H. Dingle, on "The Movements of the Stars"; on February 4, by Mr. Will T. Hay, on "Life on other Planets"; and on February 18, by Mr. F. J. Hargreaves, on "The Determination of Stellar Distances" The lectures begin at 6.30 p.m. Admission is free by tickets obtainable from Service Organizations or from the Assistant Secretary, Royal Astronomical Society, Burlington House, Piccadilly, London, W.1

Non-Solar Planetary Systems

In discussing the significance of the two planet-like bodies which are now supposed to revolve around 61 Cygni and 70 Ophiuchi, Mr. Sen writes[1] that "we find that there can be at most two planetary systems in the galactic system, on Jeans's theory". If the true number were two, or anything like two, it would, of course, be out of the question to suppose that there could be three planetary systems so near to us in space. But I do not think that the true number is anywhere near to two; in a recent letter in NATURE[2], I calculated that something like one star in six might well be accompanied by planets, in which case the number of galactic planetary systems would not be two, but some tens of thousands of millions. There is no reason why 61 Cygni and 70 Ophiuchi should not be two out of these millions of systems, so that I think that Mr. Sen's argument against my tidal theory fails.

Mr. Sen refers with approval to Banerji's modification of this theory. This makes the original sun a Cepheid which had its oscillatory instability increased by the gravitational attraction of a passing star. But a passing star cannot increase the instability of a Cepheid appreciably unless it comes very near; and as a very near approach can do all that is needed with *any* star, why introduce the added complication of supposing the star to be a Cepheid? Judging by their luminosity, all Cepheids are much more massive than the sun or 61 Cygni or 70 Ophiuchi, although, of course, this may not have been so in the remote past.

I cannot see that the discovery of the new planet-like bodies affects the present tidal theory in any way, except that, if we interpret them as true planets, they may perhaps give some slight support to my calculation[3] as to the frequency of planetary systems in space.

Non-Solar Planets and the Origin of the Solar System

THE discovery of two non-solar planets[1-3] makes it possible to check theories of the origin of the solar system.

Some time ago I pointed out that the motion of ionized matter even at the distance of the planets from the sun is affected very much more by the sun's general magnetic field than by solar gravitation, and that consequently this magnetic field may have been of fundamental importance at the genesis of the solar system[4]. A theory was put forward according to which the planets were formed of matter falling in from interstellar space towards the sun, and stopped by the action of the sun's magnetic field as soon as it became ionized by the heating due to gravitation. The theory requires that the main part of the matter become accumulated at that distance r from the sun (mass $= M_{\odot}$) where the gravitational energy equals the ionization energy eV_{ion}. Thus we have:

$$\frac{M_{\odot}m}{r} = eV_{\text{ion}}, \qquad (1)$$

where m is the mean atomic weight of the gas. The distance r equals the orbital radius of Jupiter if $V_{\text{ion}} = 12$ volts and $m = 7$ (or, through a certain correction, $m = 10$), which values are quite reasonable.

When Jupiter's mass is substituted for the solar mass in (1), r becomes equal to the distance of the large Jovian satellites, which indicates that they may have been generated in the same way as the planets. The structure of the Saturnian system also is consistent with the theory.

The invading matter probably originated from a gas cloud once surrounding the sun. If other stars have been surrounded by clouds of the same mean atomic weight, they are likely to possess similar planetary systems, the dimensions of which are proportional to the masses of the stars. Thus the 'Jupiter' of a star with the mass M (sun $= 1$) will have the orbital radius

$$r = 5{\cdot}2\,M \text{ astron. units.}$$

Observations have not determined to which components of the double stars the newly discovered non-solar planets belong. My theory requires that for a given cloud density the larger component shall have the more massive planetary system. As the components of 61 Cygni are almost equal, the largest planets of each of them should have almost the same masses and periods, so that the observed disturbance is due to both of them. For 70 Ophiuchi a planet of the larger component ought to produce the greatest effect. Thus we find:

Star	Mass	Distance of planet	
		Theory	Obs.
61 Cygni[2]	0·56	2·9	2·4
70 Ophiuchi[3]	1·1	5·7	6·8

The agreement indicates that these non-solar planets may have been formed in the same way as our planetary system.

The theory makes it probable that all stars are surrounded by planetary systems (more or less massive) of the same structure as ours. Planets corresponding to Jupiter will have the period

$$T = 11{\cdot}9\,M \text{ years.}$$

It may be worth while to look for disturbances with such periods.

Mutation and the Rhesus Reaction

RECENT announcements by Race, Taylor[1,2] and their collaborators in these columns, and by Wiener and Landsteiner[3], elsewhere, are of peculiar interest in connexion with some genetic implications of Levine's interpretation of erythroblastosis. Levine's hypothesis postulates a form of adverse selection restricted to heterozygous offspring of a particular class of matings and not usually affecting first-born. Selection intensity therefore depends both on the frequency of the gene *rh* and on the size of the family. During the summer I made an examination of the theoretical consequences of these assumptions. The results, submitted for publication in full elsewhere, led to two conclusions: (*a*) the likelihood that *Rh*(+) is the manifestation of several dominant alleles of a multiple allele series in conformity with experimental data since then established; (*b*) the possibility that all such alleles are not equally efficacious with reference to the determination of hæmolytic anæmias of the newborn or stillbirths and miscarriages associated therewith.

From a theoretical point of view the outstanding anomaly of Levine's hypothesis is the very high incidence of a gene subject to fairly intense adverse selection. If μ is the net mutation-rate to a recessive gene of frequency r from one or more dominant alleles, s being the negative coefficient of selection for the heterozygous class as a whole, the condition of equilibrium between mutation and mortality is given by the relation:

$$\mu = \frac{sr(1-2r)}{1-sr}.$$

Various considerations, including remarkably close correspondence between figures for incidence of *Rh*(−) based on samples collected from widely separated localities, justify the supposition that an equilibrium state exists. On the basis of available vital statistics with respect to general incidence of erythroblastosis and the proportion of stillbirths or miscarriages attributable to the same mechanism, we may assign a lower limit to s. We then find that μ is much higher than any single-gene mutation-rate as yet recorded in the laboratory or in the field. On the other hand, its value is not inordinately high if we interpret μ to signify the rate of mutation at the *rh* locus from *any one of a series* of 5 or more dominant alleles. Conclusions at which Wiener and Landsteiner in America and Race, Taylor *et al.* in Great Britain have independently arrived at from observation, thus tally with what one would have strong grounds for assuming to be true from purely theoretical considerations.

What is more important in connexion with further work is that the distribution defined by the equilibrium condition stated above may depart very considerably from a random distribution calculated on the assumption that selection and mutation are negligible. The appropriate equations for gene frequency analysis must therefore make μ and s explicit. They are quite straightforward, if we know s. At present, there are insufficient reliable statistics of the general incidence of erythroblastosis fœtalis or of the fœtal and neonatal mortality associated with it. By the same token there are insufficient data for evaluating precisely what contribution isoimmunization makes to the etiology of erythroblastosis fœtalis. What is certain in the light of statistics already to hand is that second or later born heterozygous offspring of *Rh*(−) mothers by *Rh*(+) fathers are far more numerous than recognizable cases of neonatal hæmolytic anæmia and associated miscarriages or stillbirths.

It is therefore pertinent to emphasize a consideration insufficiently realized by workers in the clinical field. Where the end in view is to assay the importance of serological incompatibilities as agencies contributory to fœtal and neonatal mortality, samples collected because of recorded erythroblastosis within a fraternity, and afterwards tested for the blood grouping of parents and offspring or for the anti-body titre of the mother, may be misleading. We should proceed from the opposite direction, that is, collect *entirely random* samples of offspring by parents of particular blood groups in order to determine the incidence of erythroblastosis, stillbirths and miscarriages, together with the blood groups of the offspring. Large enough samples both of matings *Rh*(+) father by *Rh*(−) mother and (as a control group) *Rh*(+) mother by *Rh*(−) father, should then give us all essential data for a just appreciation of the value of Levine's hypothesis and all relevant data for a determination both of the mutation-rate (μ) at a human locus and of the selection coefficient (s) of the *rh*–*Rh* system. Under war-time conditions, the possibility of getting such samples at blood transfusion depots is not fanciful.

An Interferometric Procedure for the Examination of Crystal Surfaces

THE accompanying photographs illustrate a high-precision interference procedure which has been developed for the examination of the contours of the surface figure on the surfaces of crystals. The method employed is an adaptation of Fabry and Perot's modification (made in 1897) of Fizeau's standard method for examining the perfection of optical flats with localized fringes. It is essentially a multiple beam interference procedure, depending for its precision on the employment of many interfering beams, and is easiest to apply to reasonably large crystalline surfaces which are moderately plane.

A transmitting high-reflecting coefficient thin silver film (reflecting coefficient about 0·85) is deposited upon the untouched crystal face by evaporation *in vacuo*. This silvered surface is then adjusted to be nearly parallel to a similarly coated good optical flat. The separation between the silvered surfaces is preferably a small fraction of a millimetre, but the actual value is not critical. A parallel beam of light from a small circular aperture illuminated by a green-filtered mercury arc is directed at normal incidence on to the silvered faces. Fringes of equal thickness form; but owing to the multiple reflexions these are extremely sharp and have an intensity distribution depending upon the reflecting coefficient in a manner identical with that of the normal circular Fabry-Perot fringes of equal inclination.

These localized fringes constitute true contour lines of the crystal surface if the optical flat is of very high precision, and the interval between a pair of fringes represents a change in surface height of half a wave. The method has been applied to the examination of the cleavage surfaces of mica, selenite and calcite, and also to a natural surface of a quartz crystal. Some striking facts have thus been revealed. Typical contours of mica and selenite are shown in the accompanying reproductions.

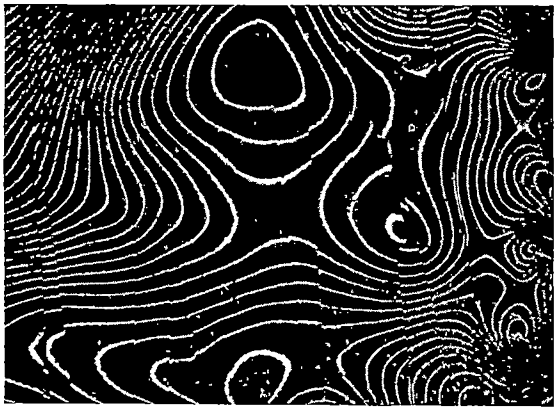

Fig. 1. MICA.

Fig. 1 shows a typical mica cleavage surface, the rea represented being about one square centimetre. ll mica surfaces so far examined reveal similar atterns. The highly advantageous intensity disribution is clearly evident. The fringes are very harp narrow lines, occupying a small fraction of the istance between orders. The strong fringes are due o the green mercury line, the weaker doublet being he yellow lines. These permit identification of orders o be unambiguous. Without going into the finer points f detail, three main features are apparent: (1) The eneral contour of the hills and dales on the surface rendered with startling clarity. (2) Sharp cleavage oundary lines appear. These represent steps of, in ost cases, a fraction of a wave-length. The smallest tep so far recorded is 40 A., which is only a few olecules. (3) The areas between the cleavage oundary lines may pass over hills and dales, but hey are highly uniform, as evidenced by the smoothess of the fringes within the separate areas.

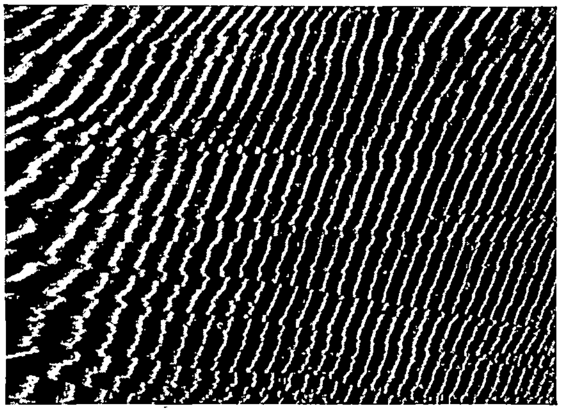

Fig. 2. SELENITE.

Fig. 2 shows in contrast a typical contour pattern or a good cleavage face of a crystal of selenite. he obvious characteristics are: (1) Absence of bigcale hills and dales as exhibited by mica. (2) Cleavge boundary lines all in the same general direction. 3) The fringes are nowhere smooth and continuous, ut are quite ragged. Examination by high dispersion hows that the ragged feature originates in the fact hat the surface exhibits a very large number of small acets differing in height by a small fraction of a ave-length.

It is clear that this experimental procedure has onsiderable potentialities in revealing the finer details of the surface structure of crystals. The highly sharpened fringes permit of very great precision, and cleavage steps of the order of but a few molecules thick can be detected and measured. This is, of course, far beyond the range of the microscope. A step only 30 A. in height could be detected.

Further details of procedure and specific results relating to mica, selenite, calcite and quartz will be communicated elsewhere.

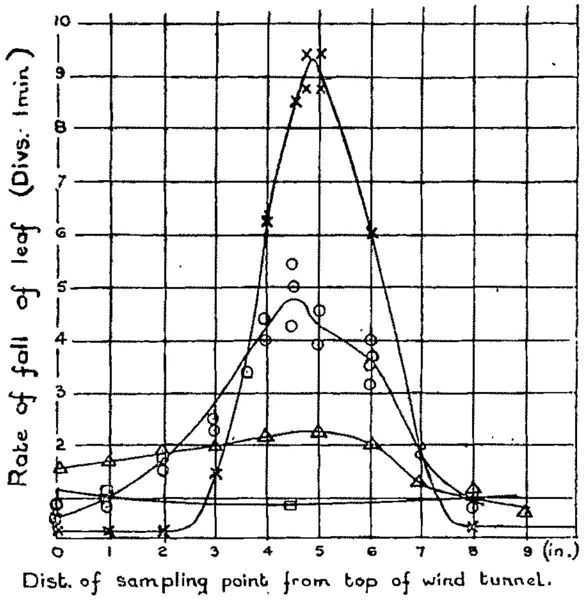
Use of Radon to Trace the Flow Pattern of Gases in Furnaces

IN the operation of furnaces, the mean mixing length, l, of the gases[1] is of importance (as it is in aircraft design) since the processes of combustion, heat transfer, and of reaction with the surface being heated depend very largely upon the mass transfer of gas in directions normal to the main flow. The method of calculating l from observations of the temperature distribution in the wake of a hot wire is inapplicable for furnaces, and most chemical methods are also precluded by the relatively high temperatures and the impurities present. The use of a radioactive gas, on the other hand, offers a method which is not subject to these difficulties, since the activity is unaffected by temperature and by chemical reactions.

A series of experiments carried out in a home-made wind tunnel (cross-section 25 cm. × 25 cm.) has shown that the method is quite practicable. A 20 millicurie sample of radon was mixed with air in a gas-holder of about 350 litres capacity, and the mixture injected at 0·15 litres/min. into the centre of the main air stream, the volume-rate of which was 4,000 litres per min. The aperture was of such size as to give the radon-air about the same linear velocity as the main stream. Samples of the gas were drawn off through probe tubes placed at various distances and positions downstream. The samples were drawn through a tower containing cotton-wool and calcium chloride, and then passed into the chamber of an inverted Rutherford-type emanation electroscope which was alternately charged and evacuated several times. The top of the chamber was then removed and a standard Ministry of Food tin, with lid bored to fit over the insulator, inserted, a fresh tin being used for each reading. In this way the effect of recoil atoms was made negligible and a very low natural leak obtained (approx. 0·17 div./min.). Curves obtained with this apparatus are reproduced, the abscissa being the vertical height of the probe point in the tunnel, and the ordinate the relative activity of the sample in scale divisions per minute. It will be seen that the curves corresponding to sampling planes near the inlet point, where the effect of the walls is small, obey the Gaussian error law sufficiently well to be used for calculation of the mean mixing length. The relative spread (½ value width) and relative maxima of the curves also show the expected order of agreement with theory.

These results were considered to justify the attempt to apply the method to furnace systems, and preliminary trials have accordingly been made in a glass-melting furnace which have shown that no unexpected difficulties arise. The method can be used



DISTRIBUTION OF RADON IN THE WAKE OF A POINT SOURCE. SAMPLING PROBE AT POSITION 1A, × ; AT 2, ⊙ ; AT 3, △ ; AT 6, □.

not only for measurements of l but also of the cross flow from one furnace port to another. By introducing the active gas suddenly it can be used for the detection of regions of very low gas velocity; and by measuring the relative activity in a single pipe after perfect mixing is attained, it can be used for metering hot raw gases continuously—a technical problem of very great difficulty and importance.

It is proposed to improve the technique by the use of an electrometer valve to increase the convenience of measurement for field work, and possibly by the development of continuous methods of removing the recoil atoms.

Our thanks are due to Dr. N. Feather, Prof. S. Russ and Mr. R. Siday for advice on the radioactive technique, and Mr. P. R. Chase for carrying out much of the experimental work; also to the Medical Research Council for the radon used in these experiments.

A New Water-Soluble Polysaccharide from Perennial Rye Grass Pasture

A WATER-SOLUBLE polysaccharide containing galactose and glucose residues has been isolated from perennial rye grass pasture. Repeated fractional precipitation from aqueous solution by alcohol and acid-alcohol followed by prolonged dialysis did not effect appreciable reduction of the high ash content (more than 30 per cent) of the polysaccharide. Since the ash consisted of calcium sulphate, it is suggested that the polysaccharide may occur as the calcium salt of the sulphuric ester of a polygalactose with one or more glucose residues incorporated in the carbohydrate moiety.

The aqueous solution of the polysaccharide was neutral in reaction, reduced Fehling's solution, an gave a positive rotation, $[\alpha]_D^{16°} + 40°$ ($C = 0{\cdot}125$)

The galactose was identified as mucic acid, m.p and mixed m.p. 214° C., and the glucose as aci potassium saccharate, which was converted to th silver salt. No other sugars were found.

All previously reported galactans appear to be o algal or fungal origin and the few known poly saccharide sulphuric esters, for example, agar fucoidin[2], etc., have been extracted from the sam sources. On the other hand, the polysaccharid herein described is of higher plant origin.

Microbiological Assay of Riboflavin

IN his letter appearing under the above title[1], D F. C. Happold criticizes the procedure used by D E. C. Barton-Wright and Mr. R. G. Booth[2] in th determination of riboflavin, and insists on the impor ance of calcium in the nutrient medium and mention the work of Chattaway, Happold and Sandford[3]. Th evidence in the latter paper to which he evidentl refers consists in an experiment in which a series increasing doses of calcium chloride was added to th nutrient medium. The authors do not seem to hav appreciated fully a limiting factor in the very lo solubility of calcium in the presence of excess phosphate at pH 6·6–6·8. The solubility product tricalcium phosphate is about 10^{-32}, but may be pe haps 10^{-31} in the presence of the other minerals co tained in Chattaway, Happold and Sandford nutrient medium[4,5].

Calculation shows that the quantity of calciu soluble under the conditions of their experiment the equivalent of 0·0028 ml. of 0·5 per cent calciu chloride in the 20 ml. of medium used, where additions ranging from 0·1 to 0·8 ml. were mad Virtually the whole of the added calcium would precipitated. It is true that the addition of calciu chloride was delayed until after sterilization of t main part of the medium, but subsequent precipit tion during the seventy-two hours at 37° may taken as certain. In the absence of precise knowled of certain factors—the time taken for such precipit tion to occur, how soon inoculation followed the pr paration of the flasks of medium, whether or n precipitation preceded the main growth of t bacteria, and if so its effect on the latter when settli to the bottom of the flasks, etc.—it is impossible state what effects were exercised by the add calcium. At least it seems certain that the dire conclusion that calcium stimulates growth of t Lactobacillus is not warranted by the experiment evidence cited.

A Penicillin-like Substance from *Aspergillus giganteus* Wehm.

THE production of antibiotic substances by several species of Aspergillus has been reported, and several have been purified or isolated[1–5]. Wilkins and Harris[6] described the production of a substance, active against staphylococci, by *Aspergillus giganteus*. A culture of the mould (kindly supplied by Dr. Wilkins) was grown on a medium consisting of malt extract, 2 per cent, peptone, 1 per cent, *M* triethanolamine buffer *p*H 8·2, 5 per cent. The antibiotic has been purified and a crystalline degradation product prepared. In all its chemical and biological properties it appears to be very similar to penicillin[7].

Although the mould produces much less pigment than *Penicillium notatum*, the yield of the antibiotic is lower and the purification no easier than that of penicillin.

It is suggested that this substance be called *gigantic acid* to indicate its source.

It is of interest that the production of antibiotics chemically similar to penicillin is not limited to the genus Penicillium, but that they are produced by at least two species of Aspergillus, namely, *Aspergillus giganteus* and *Aspergillus flavus*[3,4].

Full details of this work will be published when publication conditions permit. I am indebted to the Agricultural Research Council for a personal grant.

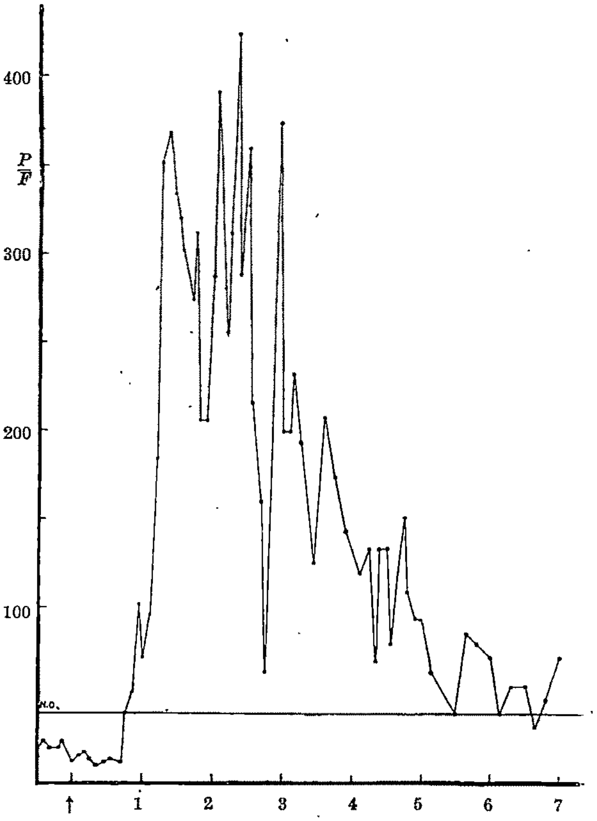
Lipæmogenic Activity of Pituitary Extracts

Frazer and Stewart[1,2] have described the chylomicron count method for assessing the level of blood-fat, and have used it to follow the effects of starvation and standard meals in man. Stewart[3], using this method, has also observed lipæmias in rabbits after severe hæmorrhage.

In the course of some experiments on rabbits we have noticed that lipæmias have frequently followed the subcutaneous injection of certain extracts prepared from pituitary glands. The work has now been discontinued, at any rate for the time being, but we have thought it worth while briefly to record our own observations as to the frequency with which these lipæmias occur and the courses they run.

The most striking feature is the extreme variation in their intensity. Thus, 27 rabbits were injected with the same amount of a pituitary extract; 4 showed no lipæmia, 21 gave maximum chylomicron counts between 5 and 10 times the normal, while 2 animals developed lipæmias so intense that they were visible to the naked eye, the particles being too densely packed to be counted. The accompanying figure illustrates the characteristic course of the lipæmia in one rabbit. Counts were made every five minutes for four hours following the injection, then at ten-minute intervals for one hour and again at five-minute intervals for a further two hours. Whenever the lipæmia could be assessed by this method, that is, in the 21 rabbits mentioned, it began between forty and fifty minutes after injection and rose rapidly to a maximum during the next thirty minutes. In animals giving the higher counts the lipæmia was sustained for an hour: there followed a general decline in count such that normal values were reached five hours after the injection, though transitory small increases occurred during the fall and for a further two hours.



$\frac{P}{F}$ = particles per microscope field; † indicates time of injection; *N.C.*, average pre-injection 5 mm. chylomicron count of 21 starved rabbits.

Marked fluctuations in the chylomicron count occurred throughout the period of observation; it was, however, noticed that the ascending portions of the curve were invariably steeper than the descending, especially during the period of maximum lipæmia. We incline to the view that this phenomenon occurs because the particles are injected into the circulation through the thoracic duct. Further, the general course of the curves suggests that fat is entering the circulation by this route for at least one hour after the initial rise.

The extracts used were prepared from desiccated frozen whole sheep pituitaries. They were good sources of thyrotrophin and gonadotrophin, but had been substantially freed of prolactin, containing less than 5 per cent of the quantity extractable from the equivalent weight of dried gland. The extracts also showed appreciable pressor and oxytocic activities.

The extracts were further found to be a potent source of the factor that raises the liver-fat content of adult guinea pigs. Control extracts prepared from sheep muscle raised neither the fat content of guinea pig livers nor the chylomicron count of rabbit blood. We therefore regard the experiments reported here as evidence for the view that these two effects may be brought about by the same pituitary factors.

Binocular Focusing on a Repeating Pattern

SOME correspondence appeared in NATURE in 1938 about the phenomenon described by Brewster[1], which is obtained by focusing on a surface covered by a repeating pattern while converging on a point nearer than, or beyond it, so that the images of different units of the pattern fall on corresponding points of the two retinæ. Paget[2] found that when he converged, the patterned surface seemed to approach to the position of the point of convergence, the units appearing correspondingly smaller. This experiment has now been tried on eight subjects, and Paget's result only obtained with four of them. They were asked to estimate, and then indicate with a ruler, the distance and size of the pattern. Two saw the images at the distance for which they were focusing, however much they squinted, and two saw them in a rather indeterminate intermediate position.

The divergent results of previous investigators of the factors underlying judgments of absolute distance seem to be due partly to differences in their experimental methods, and partly to the very limited number of subjects studied. It can be shown by using only a tiled floor or striped wallpaper, a tape-measure, and a piece of thread, that the estimate of absolute distance can vary widely with the subject and the conditions of the experiment. A satisfactory arrangement for such an experiment must provide that: (1) the illumination is constant; (2) the size of the retinal image is constant; (3) the object to be observed can be clearly focused; (4) the object fills the whole visual field so that there is nothing else with which to compare it; (5) the distance of the 'marker' used to indicate the position of the image can be accurately judged; (6) the 'marker' is not visible until the position of the image has been judged, otherwise estimates are purely relative. The apparatus of Carr and Swenson[3] neglects point 3, that of Grant[4] point 5, and that of Fischer and Löwenbach[5] points 4 and 6.

The repeating pattern fulfils all these requirements; the difficulty arises in choosing a suitable 'marker'. If a piece of thread was used, the apparent position of the pattern varied according to whether the thread ran sagittally or from right to left. In the latter case, when the thread could only be located by focusing, two of the subjects could not tell where it or the images were; but all who could make a judgment in both sets of conditions located the images nearer the point of convergence with the thread running sagittally, and therefore easy to converge upon. The two 'focusers' still saw the pattern well beyond the point of convergence. When one of the 'intermediate' subjects, who usually located the image not far from the plane on which he was focusing, held the thread sagittally at the point of convergence, he found that the pattern "floated up and sat on it", dropping down again when he removed the thread. An apparatus which uses as a 'marker' a vertical rod visible all the time therefore begs the question. The type of pattern used also affects the results; the two subjects who tested this point located vertical lines nearer the eye than a diagonal grid.

When the subjects were given a rough test for their stereoscopic acuity, their quickness and accuracy varied directly with the degree to which they used convergence for assessing distance. Variation in the observers and in the type of floating mark or grid used in the apparatus may be of importance in the interpretation of air photographs.

In my view, contrary to most recent opinion, fine stereoscopic discrimination, in some people, does depend on small changes of convergence. It is hoped to make some more refined experiments to investigate this point.

J. B. Hannay and the Artificial Production of Diamonds

IT seems to be a well-established fact that Hannay did make diamonds, and as the result of an investigation which, in my memoir[1] of him, I described as difficult, and carried out in a masterly manner. That work like this would be scoffed at, and the mere evidence that could be put forward at the time discounted, was to be expected. It will be remembered that, when the discovery of argon was first announced, there were plenty of critics ready to suggest that the announcement was made on altogether insufficient evidence, and to commit themselves to observations which no one would attempt to justify to-day.

It seems to me to be unfortunate that an attempt should be made[2] to justify Hannay's critics, rather than to find in his other investigations evidence that he really was no mere inventor, but a very clever investigator, who came to his discovery as the result of clear reasoning, followed by well-planned and boldly executed experiments. No one who has read his papers on the continuity of the gaseous and liquid states can fail to come to such a conclusion; and many of his minor investigations show insight and exceptional experimental skill.

Now there is a very definite reason why Hannay did not reply to the criticism to which Lord Rayleigh refers. In the middle 'eighties, before he was thirty years old, Hannay had entirely abandoned what may be termed academic experimental work, and thrown himself into industrial research. What he did, he put his whole heart into; and if the criticism came to his notice, it is scarcely to be imagined that it would interest him.

However, why should Hannay 'fake' a result of this kind? The letter from Ramsay to McGowan, which I publish in my memoir, shows that Hannay not only used but also made the apparatus referred to. The general experience is that errors of this kind are accidental; and as a matter of experience, we all make mistakes, even the youngest of us.

SUBDIVISION OF INSECTA PTERYGOTA INTO SUBORDINATE GROUPS

By Dr. B. N. SCHWANWITSCH
State University of Leningrad, Saratov, U.S.S.R.

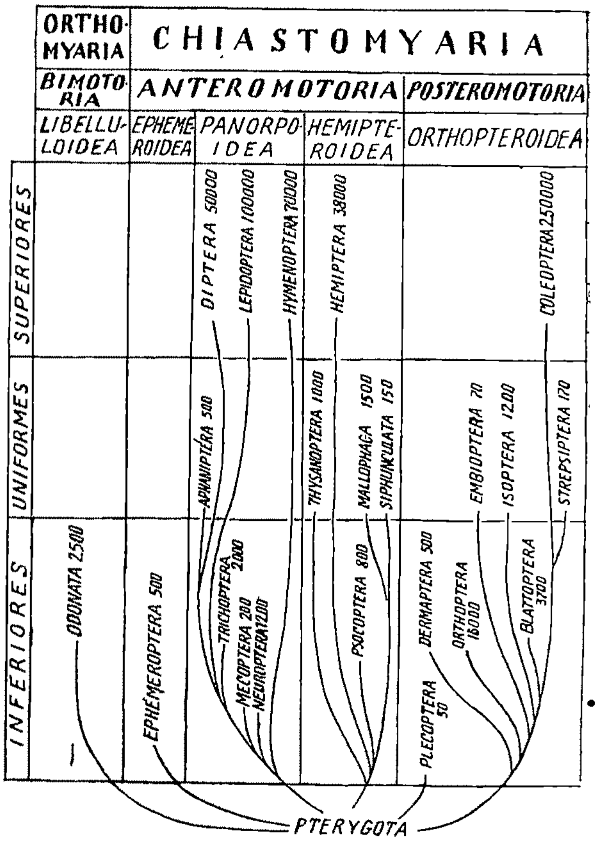
THE acquisition of wings is the most important factor upon which the unparalleled progressive evolution of insects depends. The development of liquid food feeding, though of great moment, plays only a subordinate part as compared with flight. Every order of the Insecta Pterygota shows its own type of wing, and the wing venation serves as a well-established systematic criterion, yet the functional significance of the almost endless variations in venation is as yet scarcely perceived. On the other hand, the musculature of wings shows considerable constancy in the majority of Pterygote orders, its principal modifications being few and functionally comprehensible. Therefore an attempt seems desirable to use 'the muscular motor of the wing' as a taxonomic criterion, especially for the much-needed grouping of insect orders into larger units.

There are two main types of wing motor musculature in insects[1,2]. One of them may be named chiastomyaric. In this, the levators of the wing are dorsiventral and the depressors longitudinal. The directions of the two systems thus cross over one another. Levators are lateral, depressors medial. With the exception of the Odonata, the alary musculature of all the Pterygote orders belongs to this chiastomyaric type. In Odonata the only pair of longitudinal muscles is weak, both the levation and depression being performed by dorsiventral muscles. Contrary to chiastomyaric forms, levators are medial and depressors lateral. Thus almost all the wing muscles of Odonata lie in the same direction and the muscular motor should be termed 'orthomyaric'.

On this basis the whole of the Pterygota can be divided into Orthomyaria and Chiastomyaria (see chart). In the Orthomyaria, that is, Odonata, the two pairs of wings and their motors are alike. Therefore the Orthomyaria represent a Bimotoria group. Among the Chiastomyaria, 'bimotorism' occurs only in the inferior groups like Neuroptera, Mecoptera, Plecoptera and some others, while the higher orders show a strong tendency for one pair of wings to dominate the other, with corresponding distinctions in the meso- and meta-thoracic muscles and skeleton. The process follows two directions. In Anteromotoria the fore-wing becomes dominant, while the hind one may either decrease, be lost (Cloëon), or transformed into a haltere (Diptera), and accordingly the mesothoracic motor is very much stronger than the metathoracic (Hymenoptera, Hemiptera, Lepidoptera. The opposite is the case in the Posteromotoria. Their fore-wings may either turn into elytra (Coleoptera, Dermaptera), or into halteres (Strepsiptera), or show a tendency to elytration (Blattoptera, Orthoptera), or undergo atrophy (many Phasmids), while the hind wings in some groups are either the sole or principal organs of flight. The thoracic skeleton and wing muscles are transformed accordingly, though the domination of metathorax in Posteromotoria is not so pronounced as that of mesothorax in Anteromotoria.

The latter group can be divided into three complexes of orders. One of these is the Panorpoidea, a generally acknowledged group (Neuroptera, Mecoptera, Trichoptera, Lepidoptera, Diptera, Aphaniptera) that shows a strong tendency to proboscis formation and holometabolous metamorphosis. Since the last-mentioned two characters are also present in Hymenoptera, this order should also be included in the Panorpoidea, the erucoid structure of Tenthredinid larvæ being a supplementary proof of the relationship. Another complex is the Hemipteroidea accepted by Martynov[3] under the name of Paraneoptera and comprising the Hemiptera, Thysanoptera, Mallophaga, Siphunculata and Psocoptera. Hemipteroidea differ from Panorpoidea in a still stronger tendency to proboscis formation and an almost complete absence of holometabolous metamorphosis. To the third complex of Anteromotoria, namely, the Ephemeroidea, there belong the single order Ephemeroptera.

As to Posteromotoria, they consist of only one complex, namely, the Orthopteroidea, and contain on one hand the Orthoptera in the old sense of the word (Orthoptera, Blattoptera, Dermaptera), orders regarded[4] as related to them (Isoptera, Embioptera) and the Plecoptera, which show some orthopteroid affinities as well[4]. On the other hand, the Coleoptera with Strepsiptera are also included into the complex. Besides their posteromotorism their inclusion is favoured by the affinities of Coleoptera to some extinct cockroach-like forms[5], the almost total lack of proboscis formation; and their metamorphosis, though complete, is, however, nearer to the hemimetabolous form than to that of the Panorpoids[6].



A SYSTEM OF THE ORDERS OF INSECTA PTERYGOTA BASED MAINLY ON THE STRUCTURE OF WING MUSCULATURE (VERTICAL SUBDIVISION) AND GENERAL LEVEL OF ORGANIZATION (HORIZONTAL SUBDIVISION). CIPHERS AGAINST THE NAMES OF THE ORDERS INDICATE THE NUMBER OF SPECIES IN EACH.

The Orthomyaria consist of a single complex, Libelluloidea, with the single order Odonata.

Thus the whole of the Pterygote orders is subdivided into four complexes, all of which are fairly natural. Except for the positions of the Coleoptera and Hymenoptera, the subdivision corresponds with that proposed under different names by Martynov[3], though his criteria of classification differ widely from those given in the foregoing.

Besides this, the Pterygote orders may be classified under three series shown by the horizontal division of the chart. To the Inferiores belong those orders which show general morphological primitivism, middle- and large-sized body, mostly small numbers of species (excluding Orthoptera) and paucity of biological types (excluding Neuroptera). The Uniformes combine general primitiveness with some narrow specializations (mouth parts of parasites, asymmetrical head and mouth parts of thrips, silk glands of Embioptera). Minute body size, paucity of species and biological types and a strong tendency to apterism are also typical of the series. The Superiores consist of five orders which on account of their maximum morphological specialization, enormous numbers of species and biological types and the widest variability of body size should be regarded as undoubted peaks of insect evolution.

The interrelations of the horizontal and vertical divisions of the chart make it clear that, in each of the three main complexes (Panorpoidea, Hemipteroidea, Orthopteroidea), evolution follows the same course; namely, starting with primitive groups like Mecoptera, Psocoptera or Blattoptera, it leads to the maximum abundance of the forms of life in the progressive orders of Superiores on one hand and to the narrow specialization of the Uniformes on the other. Thus a definite structure is typical of each complex.

The system described is on one hand based on the types of wing mechanism, mouth parts and metamorphosis; on the other, it attempts to take into account the general 'height' of organization, and thus make a distinction between primitive, regressive and progressive orders of Pterygote insects.

GEOLOGY IN THE WAR AND AFTER

DR. E. B. BAILEY, in a lecture to the Royal Philosophical Society of Glasgow, delivered on November 17, on "Geology in the War and After", dealt in particular with the work of the Geological Survey of Great Britain, of which he is director. The main war aim has been to give useful advice on: (1) home mineral resources, so as to meet essential needs with economy of shipping and foreign currency; (2) underground water, for new aerodromes, camps and factories; (3) subterranean facilities, for storage and personnel. Coal is the main mineral asset of Great Britain. Two interesting current problems occupy a considerable share of the Geological Survey's time: first, the resurrection, with modern equipment, of coal outcrop working, and second, the correlation of coal seams. Correlation work has been intensified because confused nomenclature impedes progress, that may be expected from the recent unification of ownership in the hands of the State. In its coal work, the Geological Survey co-operates closely with another branch of the Department of Scientific and Industrial Research, namely, the Fuel Research Board, the concern of which is with the quality of the coal seams.

Iron comes second only to coal in importance. Iron ore at present is mostly won from bedded ores in the English Midlands, exploited, as in the case of coal crops, with mechanical diggers. The Survey has done much to help in this wide field. Elsewhere it has directed attention to valuable veins of low-phosphorus iron-ore and has guided their successful development. In regard to non-ferrous metals, the Survey has had successes, but perhaps it is wiser not to particularize. Among non-metallic vein minerals, special attention may be directed to fluor. The Survey warned the steel industry of a possible fluor shortage, and played its part in averting trouble. One important step was to interpret the shape of a particular fluor body, which allowed of ordered replanning of mining operations. In this matter Canadian miners, now sappers, helped greatly by teaching British comrades a novel technique. Felspar may be mentioned here, as a mineral in which, through Survey advice, Great Britain has passed from zero production to self-sufficiency, even in the most exacting grades required for dentures.

Sand and gravel are, of course, always in demand. The year 1939–40 was 'sand-bag year' for London. The coming of war called for rapid reinforcement of existing buildings, and the Survey indicated the particular parks and open spaces where sand-bags could be filled. The Civil Defence authorities have estimated the resultant saving at £125,000. Moreover, external roads and railways were freed for other traffic. Sand of suitable quality for the manufacture of optical glass had been located by the Survey so long ago as 1921, and its significance constantly stressed in the proper quarter during ensuing years. The reward came in 1940, when all Continental sources of this strategic mineral passed into enemy hands. Mica, essential in electrical apparatus, has also been found, of good quality and useful amount.

The importance of the Survey's store of digested information in regard to underground water and underground possibilities of excavation is self-evident. Many inquiries also have been answered upon matters of overseas geology. As a rule, the information has been supplied from the Library; but one member of staff has the privilege of serving as geological adviser in the Central Mediterranean Force, and another was able to visit Malta last spring.

In conclusion, Dr. Bailey expressed the hope that geology would play as useful a part in reconstruction as in war, and that geologists would remember in the future, as in the past, that man does not live by bread alone; in other words, once victory has brought the present emergency to a close, geologists will return to wrestle with the rocks to win from them treasures, intellectual as well as material. It is of happy augury that a geologist, Prof. A. E. Trueman of the University of Glasgow, has been appointed to the small committee that leaves for West Africa in the New Year entrusted with a mission that depends for success upon a combination of good-will, good sense and technical knowledge.

SCIENTIFIC AND INDUSTRIAL RESEARCH IN AUSTRALIA

THE sixteenth annual report of the Department of Scientific and Industrial Research, Commonwealth of Australia, covers the year ended June 30, 942. A large part of the Department's activities is now devoted to the solution of problems arising out of the War, and to assistance and advice to various Government Departments and other institutions and organizations concerned with the war effort, reference o which activities is confined to brief statements or omitted entirely. Among such investigations are those on flax production, vegetable seed production, the possibilities of native and exotic Australian plants or rubber production, the planting and testing of rubber-producing plants from various parts of the world, the storage of foodstuffs and wool and the development of special rations and high vitamin-content extracts for the use of the various Services.

Plant investigations in the field of vegetable fibres have included studies of the microbiology of dew retting and of the actual process of retting to ascertain whether improvement is possible in practice, investigations on pastures and weeds as well as on fruit, although that on general storage disorders has been curtailed. Potato investigations have included a study of virus disease, and a study of the effects of virus *X* on yield has been concluded. Tobacco investigations have been curtailed; but drug-plant investigations have included the extraction of hyoscine and atropine, opium alkaloids, digitalis, ephedrine, ergot, quinine and strychnine, santonin and felix-mas, pyrethrum and native plants as sources of medicinal drugs.

Entomological investigations have covered insect pests in stored wheat and in stored wool, including tests of possible control methods, the insect control of noxious weeds, as well as sheep blow-fly. Other work has been concerned with the development of fly and mosquito sprays, the control of the Australian plague locust, and tests of insecticides designed to control the red-legged earth mite in pasture land. Nutrition investigations at the Animal Health Research Laboratory, Melbourne, have covered pleuro-pneumonia of cattle and mastitis in dairy cattle, while the McMaster Animal Health Laboratory has continued its studies on the administration of phenothiazine, investigations on the efficiency, and economy in the use, of anthelmintics and on external parasites of sheep.

The field staff of the Division of Soils has continued its work, but on a smaller scale, and the Division has also continued spectrochemical work on soils, including a survey of the metallic composition of surface soil at the Waite Institute, problems of anion exchange, with particular reference to the fixation of phosphoric acid, and the determination of small amounts of copper in soil and its availability to plants. No new major lines of investigation have been commenced by the Forest Products Division. Work has continued on the study of fundamental problems on behalf of the Australian pulp and paper industry on the investigation of wood structure in relation to properties, timber seasoning and timber physics, and on wood preservation, as well as on veneering and glueing.

The re-organization of the Division of Food Preservation and Transport has been completed, and all its officers are now engaged on problems of direct importance to the war effort, and chiefly those relating to the canning and drying of foodstuffs. Many investigations on cold storage have been temporarily abandoned. The great expansion in vegetable canning has raised many problems in general canning technology which the Division has been called upon to solve, and the Division undertook a broad investigation into the effect of each step in the canning process on the loss of vitamins in canned vegetables, especially the green-leaf vegetables, cabbage and silver beet. The canning of bacon rashers has been a major investigation. The problem has been to give canned bacon a heat treatment adequate to prevent spoilage and yet not so severe as to destroy the quality of the pack, particularly in relation to texture and form of the rashers. Investigations into substitute materials for the manufacture of foodstuff containers have been carried out. With regard to dried foodstuffs, investigations during the year have been concerned with dried eggs and vegetables. In connexion with experiments on skin coatings for apples, nine different fungicides are being tested for use as control agents to prevent mould waste. Fruit storage investigations on apples have covered the preparation of emulsions of wax, oil, and mixtures of wax and oils, and of their effects on water-loss from fruit and on the resistance of the fruit to the diffusion of oxygen and carbon dioxide. Fundamental work is being conducted on the effect of the thickness of various skin coatings in relation to the size, maturity and the variety of fruit and the temperature of storage.

Fisheries investigations have covered a wide range with a view to the possible development of pelagic fisheries, including investigations on tuna, pilchards and anchovy, and the improvement of methods of mass catching of inshore fish such as salmon for cannery purposes. A survey of the distribution and biological characteristics of edible and other sharks has been inaugurated with the view of stabilizing or, if possible, increasing the supply of oils rich in vitamins from the recently established successful fish-oil industry. Research on agar has been intensified, and studies have been commenced on the preparation of carrageen (Irish moss).

The activities of the National Standards Laboratory have again been largely directed to defence work, including the examination of gauges and measuring equipment, calibration of testing machines, the testing of optical munitions instruments, measurement of the optical properties of melts of optical glass manufactured in Australia, and pyrometry calibration for the Ministry of Munitions. The Aeronautical Division has been increased considerably during the last two years, and is co-operating closely with the Australian Advisory Committee on Aeronautics. The development of methods of construction with synthetic resins is proceeding satisfactorily, and the position in regard to testing equipment for engines has been considerably improved. The Instruments Section has designed and constructed a noisemeter, a recording accelerometer and resistance strain gauges. The Division of Industrial Chemistry has carried out further investigations on the Freney-Lipson process for reducing the shrinkage of wool as well as on the Woolindras process. Attention has also been concentrated on fellmongering, including a physical method of following the depilation of sheepskins, the mechanism of sweating, chemical sterilization of sheepskins and identification of bacteria capable of depilating sheepskins. Attention has also been given to physico-chemical investigations on the flotation of sulphide and non-sulphide ores, and to foundry sands; and an investigation on ethylene as a starting material for the synthesis of commercially valuable organic chemicals has been initiated, including the manufacture of ethylene chlorohydrin. Investigations in the field of synthetic resins have also been commenced, and the building up of a research organization for dealing with friction, lubrication, bearing and wear problems has been continued under which investigations on the theory of metallic friction and the role of shearing and ploughing and on the friction of thin metallic films have been carried out. Other investigations in this field have been concerned with the testing of bearing metals and bearings, the mechanism of lubrication, extreme pressure lubricants, cutting fluids, and the development of lubricants for drawing and pressing, as well as the lubrication and wear of piston rings and cylinders, and the wear and oil-contamination of producer-gas vehicles.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Saturday, December 18

Institute of Physics (Electronics Group) (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. L. Jánossy: "Cosmic Rays".

Royal Photographic Society (Scientific and Technical Group) (joint meeting with the Association for Scientific Photography) (at 16 Prince's Gate, South Kensington, London, S.W.7), at 2.30 p.m.—Exhibition of Scientific Photographic Apparatus.

Monday, December 20

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Mr. Evert Barger: "Some Problems of Central Asian Exploration" (Tenth Asia Lecture).

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6 p.m.—Mr. W. Muckle: "Some Considerations in the Application of Light Alloys to Ship Construction".

Tuesday, December 21

Union des Ingenieurs et Techniciens de la France Combattante (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 4.30 p.m.—Colonel P. Baranger: "La Reconstruction et l'education technique".*

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Dr. Otto Friedmann: "Some Czechoslovak Folkways".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Science Teacher at the Flint Day Continuation School—The Director of Education, County Education Offices, Mold, Flintshire (December 24).

Lecturer in Science at the F. L. Calder College of Domestic Science (to be responsible for the teaching of Science applied to Domestic Subjects and of Hygiene)—The Director of Education, Education Offices, 14 Sir Thomas Street, Liverpool 1 (December 27).

Assistant Teacher of Mathematics at the Selby Art School and Technical Institute—The Secretary to the Managers, Education Offices, Garforth, near Leeds (December 31).

Specialist Teacher of Stammering—The Director of Education, Education Offices, Burnley (December 31).

Lecturer in High Voltage Engineering, and an Assistant Lecturer in Mechanical Engineering—The Registrar, College of Technology, Manchester 1 (December 31).

Teacher in Engineering Subjects (possessing Graduate or equivalent qualifications in Mechanical Engineering and Industrial experience) at the Melton Mowbray and District County Technical College—The Director of Education, County Education Office, Grey Friars, Leicester (January 6).

Graduate (temporary) for Mechanical or Civil Engineering Subjects, together with Mathematics, at the Denbighshire Technical College, Wrexham—The Director of Education, Education Offices, Ruthin, Denbighshire (January 8).

Acting full-time Demonstrator of Anatomy—The Dean, Medical College, St. Bartholomew's Hospital, London, E.C.1 (January 11).

Entomologist in the Department of Agriculture, Salisbury, Southern Rhodesia—The Official Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (January 31).

Lecturer on Physics—The School Secretary, St. Mary's Hospital Medical School, London, W.2 (February 1).

Assistant Engineers (Civil) for the Government Railways i West Africa—The Ministry of Labour and National Service, Centr (Technical and Scientific) Register, Advertising Section, Alexandr House, Kingsway, London, W.C.2 (quoting Reference No. E.778A).

Dockyard Manager for the Sudan Railways (candidates should b fully trained Marine Engineers holding University Engineering Degre or A.M.I.Mech.E. or A.M.I.N.A.)—The Ministry of Labour an National Service, Central (Technical and Scientific) Register, Adve tising Section, Alexandra House, Kingsway, London, W.C.2 (quotin Reference No. C.1866a).

Assistant Master or Mistress to teach Geography, and a Assistant Master for Engineering, in the Burton-upon-Tre Technical Institute and Junior Technical School—The Secretary an Director of Education, Education Offices, Guild Street, Burton-upo Trent.

Chief Technical Officer—The Secretary, Warwickshire W Agricultural Executive Committee, 6 Guy's Cliffe Avenue, Leamingt Spa.

Teacher (temporary) of Mathematics to junior engineeri students—The Principal, County Technical College and School Art, Newark, Notts.

Graduate Assistant to teach Physics (industrial and teachin experience desirable), and a Graduate Assistant for subjects u to Higher National Certificate standard in Mechanical Engineerin (candidates must have had practical experience in Engineering a be able to teach Electrical Engineering to the Ordinary Nation Certificate standard), at the West Hartlepool Technical College a Technical Day School for Boys—The Chief Education Officer, Educ tion Offices, Park Road, West Hartlepool.

Speech Therapist in School Clinics for the Remedial Treatme of Stammering and other Speech Defects—The Director of Educati Education Offices, Todmorden, Yorks.

Graduate Assistant Master for Engineering Subjects wi Mathematics in Day Technical School and Evening Institute—Th Principal, Technical Institute, 28 Beckenham Road, Beckenham, Ke

THE IMPERIAL AGRICULTURAL BUREAUX

IT is a pleasant occupation in these times, when so much is being talked about imperial and international co-operation, to study the workings of an organization built up by such co-operation, and the Imperial Agricultural Bureaux furnish a very relevant example. They were set up in their present form by the Governments of the British Commonwealth in 1928 on the recommendation of the Imperial Agricultural Research Conference, and the Governments have been sufficiently satisfied with the organization for them to accept the recommendation of the British Commonwealth Scientific Conference of 1936 to increase their number.

The agricultural bureaux were primarily set up to help research workers in the British Empire to keep abreast of their subjects. All research workers know only too well how many publications may contain information of importance to them, how much they would cost if they had to buy them all, and the great diversity of language used. This difficulty is serious enough for a research worker in a large central research institution, but it becomes insuperable in small isolated institutions. The primary function of the bureaux is to lighten the difficulties of research workers in agricultural institutions by various means: by issuing regular abstract journals and bulletins dealing with recent advances in knowledge in specific subjects; by providing information needed on specific points, with the corollary that the workers themselves must be aware of the existence of the bureaux and have sufficient confidence in them to ask for this information; by arranging meetings between research workers whenever sufficient of them can be brought together; and by acting as advisers or host whenever any of them can make use of that service.

The bureaux have thus a very difficult function to fulfil, as they must contain on their staffs men competent to understand the sciences in which advice is wanted. They cannot, therefore, be a staff of mere abstracters, nor simply secretaries to farm out papers to a panel of abstracters. The men must have experience in agricultural research, so that they can appreciate the peculiar difficulties of any particular subject, but it is equally essential that they should keep abreast of all new ideas. Each bureau was set up alongside a leading research station devoted to that science, to help the bureau staff keep their own knowledge up to date, and to allow any specific problem to be rapidly referred to a leading specialist when necessary.

It was also necessary to ensure that the Empire research workers using the bureaux should have accurate knowledge of what the bureaux can do, and confidence in their competence to do it; and it was accepted that personal acquaintance with the bureau itself was the best way of giving them that knowledge. It was mainly for this consideration that the Governments placed all the bureaux in Great Britain, the country visited by the greatest number of Empire workers.

The bureaux were set up by the Governments of the British Commonwealth, who are jointly responsible for their finance. An Executive Council composed of a nominee from each Government contributing to the fund and of a secretary, who is also in fact the secretary to the Imperial Economic Committee, is responsible for their administration. The Council's work was reviewed by the British Commonwealth Scientific Conference in 1936, and a further review should have been made in 1941, but the War prevented this. In consequence the Executive Council set up a committee, under the chairmanship of Lord Hankey*, to undertake this review, adding in the terms of reference the request for it to report on how the activities of the bureaux can be extended to be of greater service to the British Commonwealth, and making the significant statement "and in general to the United Nations". For these agricultural bureaux have no counterpart elsewhere in the world, and although they were set up for the sole purpose of helping agricultural research workers throughout the Empire, their publications have a considerable circulation throughout the world, and their work is sufficiently highly appreciated for them to be frequently consulted by foreign workers.

At the present time the bureaux fall into two categories: those for entomology and mycology, which were already in existence before the Executive Council was set up, and the ten that have been set up since. These two earlier bureaux, set up under previous Imperial Conferences and financed by the several Governments jointly, have a wider function than the others, for they not only abstract the literature but also identify any pathological insect or fungus found in any part of the British Empire. This makes it necessary for them to have trained systematists on their staffs with adequate laboratory accommodation; to signify this wider function their names were changed from Bureaux to Institutes when they were taken over by the Executive Council. The Entomological Institute is equally concerned with plants and animals, as insects are serious pests on both; but fungal diseases are primarily plant diseases and, in consequence, the Mycological Institute has extended in the direction of plant pathology, and now not only covers the fungal diseases proper but also the virus and bacterial diseases as well. But there are fungal diseases of animals and humans, and here Lord Hankey's Committee found that the Institute was in fact abstracting some papers on medical mycology without any clear indication of what use would be made of these abstracts, as the medical profession was apparently unaware of its existence and, in fact, was barely in need of them since the Bureau of Hygiene and Tropical Diseases issued suitable abstracts on many aspects of medical mycology for the profession. Already a sub-committee has been set up under the Medical Research Council to examine the whole question of abstracting these papers, and the much more serious one of ensuring that medical nomenclature is in line with present-day mycological nomenclature.

Originally eight bureaux were set up directly under the Executive Council to deal with the various groups of agricultural sciences, namely, animal health, animal nutrition, animal genetics, soil science, pasture and forage crops, plant genetics, horticulture and agricultural parasitology (helminthology), to which were added, just before the War, dairy science and forestry. All these bureaux deal with specific branches of agricultural science and, on the whole, meet the needs of the scientific research workers admirably, as they themselves are usually working on one or two of these specific sciences. But there is no bureau for general husbandry, a branch of knowledge barely accepted in Great Britain as a part of agricultural science. The Committee recommends setting up such a bureau, a recommendation which surely should be accepted, as it will involve making an extremely interesting experiment that can profitably be watched by the agricultura research institutes in the country. The main field of general husbandry, excluding economics, is in fact covered by the existing bureaux, but their publications are already so voluminous that it is practically impossible for any one person even to skim through their abstract journals. Nor is it any bureau's business to stress those points of importance for the practical farmer.

The proposed bureau would, therefore, largely duplicate work done by the existing bureaux, and by the Bureau of Soil Science in particular, for on the scheme suggested in the report most of the subject considered suitable for the new bureau fall unde crop husbandry, which the Bureau of Soil Science already covers fairly thoroughly. The value of the new bureau would rather lie in its skill in selecting information lying on the borderline between crop and animal husbandry, but it will have to face the supreme difficulty for a bureau that there is very little literature dealing with these borderline subject owing to their comparative neglect in the development and organization of agricultural research.

One of the greatest benefits a bureau of general husbandry could give to Great Britain is to map out clearly the field of work it can genuinely cover, for once the field has been recognized and defined, th Ministry of Agriculture and the Agricultural Research Council can modify their research policy to allow such a field to be adequately covered. In Great Britain the experimenters in this subject are the progressive farmers, and the descriptions of their methods given in the popular farming journals are usually woefully inadequate for an appreciation of the value and limitations of the work carried out. The bureau might easily have to consider what criteria should be used for judging the value of method tried out on a farm, and this investigation, in itself, would be one well worth undertaking.

There is a further field of imperial agricultural co-operation which could be profitably developed, namely, that concerned with the making of plant collections of value to the plant breeder, and their preservation when made. The United States and the

U.S.S.R. have each organized many expeditions for the express purpose of making such collections, and just before the War the Executive Council of the Imperial Agricultural Bureaux expanded its scope by financing such an expedition to South and Central America for the collection of wild varieties of potatoes; a collection that may become of outstanding importance, as one of the surprising results of the War has been the way the potato has invaded countries, particularly in the Mediterranean, that barely knew it before, and if this crop is to remain in these countries it will be necessary to raise varieties uited to their conditions.

The development of machinery for ensuring that these collections, once made, are not dispersed is much more difficult, and the Hankey Committee recommends that the Executive Council should interest self in this problem and be able to furnish the next British Commonwealth Scientific Conference with an accurate picture of the collections in existence. The problem might become urgent at any time, as certain institutions throughout the Empire have already made such collections, and if for any reason one of hese institutions had to give up carrying on its collection, or even to reduce it, there is no organiza- ion to save the collection from dispersal or loss. These collections obviously are imperial assets, for hey may contain wild species of little value at the present time but with characters of great importance or other centres or other times. That such collections re international assets as well, so that this is enuinely a problem for international co-operation, no excuse for the Governments of the British Empire not setting up a co-operative organization to feguard such collections wherever they may be.

The creation and preservation of such large living ollections of plant species has thus just begun to be field of imperial co-operation, but, as already ressed, it must also become a field for international -operation, if for no other reason than that it will a very potent instrument for raising the standard living in those countries suffering from chronic alnutrition. Such an organization is, therefore, lmost an essential corollary to the 'freedom from ant' clause in President Roosevelt's famous four eedoms, and to the relevant sections of the Atlantic harter and the Hot Springs Conference.

LIBRARY SERVICE IN GREAT BRITAIN

THE detailed report on "The Public Library System of Great Britain" prepared by Mr. L. R. cColvin for the Library Association, which was blished in September 1942 (see NATURE, March 20, 43, p. 317), has now been considered by a special mmittee of the Library Association appointed by e Council of the Association for that purpose. This mmittee, after considering the report and comments ereon from branches and sections of the Library sociation, public library committees and other erested groups and individuals, has presented its port to the Council; and an official statement of the Association's proposals for the re-organization and development of the public library service of Great Britain has now been issued*. The proposals can thus be fittingly considered against the plan for educational reform now before the nation, with the enhanced demands on the public library service which such reform is likely to stimulate. Equally important, the proposals throw some light on the broad question of local government efficiency and reform, on which opinion is not the less concerned on account of the Government's refusal to consider the matter during the War.

On the latter question, it is unnecessary to remark more than that while the Government may decline to consider local government reform as a whole, we are unlikely, without some definite action, to obtain the improvement in public library services and facilities which is not only desirable but also probably essential if the full advantage of the new educational proposals is to be reaped. Merely to remove the permissive stumbling block in the Acts of Parliament by which public libraries exist will not carry us far when the resources of many local authorities are so small, and an attempt to deal with the regional question alone might well prove an obstacle to subsequent more fundamental reform.

Without recapitulating the conclusions of Mr. McColvin's report, it may be recalled that his survey gave an outstanding impression of generally unsatisfactory provision and of a badly organized service. Even the best administered and supported libraries in Great Britain are still unable to realize the reasonable ideals of their own committees and officers. The wide variations in standards of provision in different areas are depriving many men and women of educational and cultural opportunities which others enjoy. The service is often most defective where it would be most valuable. The permissive principle stands condemned; and many local authorities appear both incompetent as well as inadequately provided with resources so far as library services are concerned.

The Council of the Library Association in its statement follows closely the conclusions of the McColvin report. There are, in its view, four paramount conditions for the development of sound library service throughout Britain. First, the provision of adequate services by suitable library authorities must be made compulsory. Secondly, there must be an appropriate department of the central government responsible for guiding, encouraging and co-ordinating the work of local library authorities and insisting upon their efficiency. Thirdly, all local authorities must be made financially able to attain efficiency; and fourthly, the composition and size of local government areas must be such that the best results are made possible.

In regard to the essential requirements of any system of library service, the statement makes five points. An adequate service must be available to everyone, irrespective of where he may reside, and must include not only reasonable access to appropriate service points, but also the right and the opportunity to draw upon whatever wide resources of books and professional services each individual may require. Every accredited person should be enabled freely to borrow books from, or consult books in, any public library, regardless of his place of residence or employment. The library service should be so organized and provided that it can meet all the legitimate requirements of the community for books and information. Libraries must be controlled by library committees of men and women chosen for their interest in the service and their appreciation of its possibilities, and responsible directly to their local authorities. Finally, libraries must be staffed by capable and experienced chief officers with sufficient suitable and qualified assistants.

---

* The Public Library Service: its Post-War Reorganization and Development. Proposals by the Council of the Library Association. Pp. 16. (London: Library Association, 1943.) 6*d*.

The Library Association holds, and we think rightly, that the public library is essentially a local service, and one that should be intimately related with, and responsive to, local needs. Nevertheless, it considers that each library authority's area must embrace a socially cohesive unit, a normal natural congregation of people, and be well related to their ways of living, interests and occupations. In general, the population of a library area should be between one quarter and three quarters of a million, and the area will embrace not only the nucleus large town but also all the surrounding area which is closely related culturally and commercially. This, it is recognized, involves reform of local government areas and functions.

Failing the creation of a new Ministry or Government Department concerned with libraries, museums and other cultural matters, the statement urges that the Board of Education should be made responsible for guiding, co-ordinating and encouraging the development of local library services, but that this responsibility should be exercised through a new and distinct library department of the Board. The officers of this department should be appointed specifically for, and engaged solely upon, library matters. Grants to library authorities from the national exchequer will be necessary to make possible the provision of adequate library services throughout the country, but such grants must be made contingent upon the maintenance of sufficient suitable service points, satisfactory expenditure on books, the employment of sufficient and appropriately qualified staff and payment of agreed national scales of salaries for all grades.

According to the McColvin Report, reference library work is the outstanding failure of librarianship in Great Britain. The Association's statement proposes that a limited number of existing large reference libraries should be specially developed as regional reference libraries. All local authorities should maintain suitable special collections which would form centres for information and bibliography in their respective special spheres for the benefit of the whole country. The National Central Library should be strengthened and developed, and fully supported by adequate grants from national funds, to provide an efficient system for the interchange of the more specialized, older and less readily obtainable material. Both local provision and more comprehensive boo stocks should reduce other inter-library lending to minimum, but the National Central Library shou maintain the appropriate union catalogues, devel and maintain co-operation between libraries of kinds, encourage and co-ordinate the development special libraries, act as a national centre for bibli graphical information, organize international loar and act as a centre and clearing-house for bibli graphical information regarding the literature foreign countries. The cataloguing of books and t provision of necessary bibliographical assistance readers and library staffs should be undertaken on national basis by a central cataloguing departme which could appropriately be part of, or clos associated with, the National Central Library.

Passing over the detailed discussion of the questi of qualified staff, the general argument of wh should be assured of the support of scientific worke we note that an adequate and efficient public libr service is regarded by the Library Association a necessary background to any scheme of adult edu tion. The public library is not to be regarded primar as a part of the formal educational machinery, a its place in the community is well indicated in t section of the statement. Welcome emphasis is l on the importance of relating the public libr service as closely as possible to all other types libraries, such as those of universities, governm departments, scientific and research institutions, e and the national libraries. It may well be hoped t the attention now being given to rehabilitation reconstruction of libraries all over Europe may l to more attention being given to the fundame problems of library co-operation and relations tween special and general collections. The War clearly stimulated closer co-operation, but it sho be remembered that inter-library loans are expen and intrinsically inefficient. Our object should b create the conditions in which such loans are redu to the minimum.

There can be no doubt that the Library Associa is right in its affirmation that post-war Britain need and demand a better library service than yet been fully envisaged by local or national aut ties. It will be remembered that in "Redb University", Bruce Truscot stresses the import of the university library in stimulating though undergraduates. Development and expansion o university libraries to meet the post-war situation scarcely be entirely without reference to the reorg zation and development of the reference lib system, or to the special libraries, if only becau the difficulties and problems in the distribution replacement of stocks, particularly of scientific technical periodicals and the like, to which reference was made at the recent conference hel the Association of Special Libraries and Inform Bureaux. The Library Association thus c ground of the closest interest to scientific wo and their support as citizens should be assure the thorough revision of the law relating to p libraries required to implement the proposals o Association.

THE QUANTITATIVE ASPECT OF PHYSIOLOGICAL REGULATIONS

Physiological Regulations

By Prof. Edward F. Adolph. Pp. xvi+502. (Lancaster, Pa.: Jaques Cattell Press, 1943.) 7.50 dollars.

THE maintenance of relatively constant internal conditions in the face of a fluctuating external environment is perhaps the most characteristic feature of living, as opposed to non-living, systems. Such constancy, however, is only achieved and maintained by active regulatory processes on the part of the animal itself, and an animal only survives in so far as its 'physiological regulations' are competent to oppose and nullify any threatened change in its internal state. All physiological processes, with the exception of reproduction, appear, in the long run, to be devoted to this end; and the physiologist has come to define life as a perfectly integrated series of physiological regulations.

While the existence of physiological regulations has been apparent to everyone, and the physiological machinery by which they operate has, to some extent, been dismembered and examined, there has so far been little or no quantitative study of regulations as such. Prof. E. F. Adolph, in the United States, inspired by the pioneer work of J. S. Haldane and L. J. Henderson, has devoted many years to the measurement of physiological regulations, and his methods, results and ensuing philosophy are now available in this large monograph.

To most physiologists the study of a physiological regulation would imply an inquiry into the machinery —the organs, nerves, hormones and so on—involved. We may say at once that there is nothing of this in Adolph's book. His concern, as he clearly defines, is simply to measure the speed, sensitivity and range of regulatory processes without any consideration of the anatomical and physiological mechanisms by which they are effected. In short, he is interested in what the animal does, but not in how it does it. In general terms, his method is as follows. Any bodily factor which is subject to regulation is called a "component". Components are of diverse kinds; there are chemical constituents, such as water, glucose, oxygen; there are physical constituents, such as heat; there are activities, such as heart-rate. In the case of most components there is a continual turnover during life, and the total content of component is regulated by a balanced adjustment of the rates of gain and loss. The requisite data concerning the regulation of any given component are obtained in the following way. An increase or decrease in the total content of the component is produced by experimental means; this increment is called the "load" and it may be positive or negative. Having established a measured load, the time-course of the recovery process (regulation) is followed by determining the total content at intervals until it returns to normal; if possible the coincident changes in the rates of gain and loss are also followed. These measurements, repeated over as wide a range of loads as the animal will tolerate, provide all the data that are required. From the data a number of correlations can be established between the various variables.

Although some eight or nine different correlations were found to have their individual uses, two of them seem to be of particular value in assessing and characterizing the regulation; they are the equilibration diagram and the velocity quotient. The equilibration diagram is a graph plotting (*a*) rate of gain of component, and (*b*) rate of loss of component, against load. Zero load is placed in the centre of the abscissa and positive and negative loads extend out on either side respectively. At zero load the component is "in balance", rate of gain equals rate of loss, and hence the gain and loss curves always intersect at this point. If gain and loss cannot be separately ascertained, then rate of total change is plotted against load. It turns out that rate of gain and rate of loss are more or less directly proportional to load, though the proportionality is different as between gain and loss and as between positive and negative loads. In other words, the curves of the equilibration diagram tend to be straight lines radiating at different slopes from the point of intersection at zero load. In each case the steeper the slope the more prompt and sensitive is the regulatory process which it represents. The slope of the curve is given by the ratio rate over load; this ratio is the "velocity quotient", and it is a useful unidimensional measure for the efficiencies of the several regulatory processes concerned in the total regulation. The quantities concerned are measured in physiological units, as percentages of the initial total content, so that the equilibration diagrams and velocity quotients in different individuals, in different species, and even of different components, are all directly comparable.

Having thus shown the regulation at work and quantitatively characterized it, Adolph prefers to leave it at that, believing that any inquiry into underlying physiological mechanisms leads to theories of causation which hamper the honest straightforward assessment of the regulation *qua* regulation. In fact he is opposed to any discussion of causation in this connexion, arguing that any consideration of how an animal does things leads to preconceived ideas as to what it ought to do in certain experimental circumstances, and this limits, and may even distort, observation of what it actually does do.

Two thirds of the book is devoted to an exhaustive account of the regulation of the water-content of the body. Water is taken by Adolph as a type component to illustrate his methods in detail; it must therefore be dealt with fully, but, even so, much of the discussion (not the data) in this section could have been condensed; there is much needless repetition and interest flags (to be revived in later chapters).

The methods devised for water are then applied to other components—heat, glucose, lactate, carbon dioxide, oxygen, heart-rate, blood pressure—and are even stretched to cover tissue repair and nervous excitability. Equilibration diagrams are constructed for all these components; the data are mostly taken from the published work of others, the only novelty of the author's method lying in the handling of the data.

The general outcome is that the qualitative pattern of regulation is the same for all components, namely, by appropriate adjustments of the rates of intake or output or both. Indeed, given a turnover, it is difficult to see how it could be otherwise. Adolph makes much of the fact that the general pattern of regulation is always the same, even though the components studied are such diverse entities as water, heat and heart-rate, and even though the physiological mechanisms employed may be totally different in different species. Here one may remark that if, as he insists, the investigation is to be confined to the overall response of the whole animal, with no consideration of the internal mechanisms involved, then it is scarcely surprising that only a broad and all-embracing pattern can be discovered. There are, of course, marked quantitative differences in the regulations of different components, and of the same component in different species. There are many interesting details to be found here, too numerous to mention; a large number of previously recorded but scattered and forgotten facts are brought together in a new context.

Thus it is interesting to note that, on the basis of quantitative difference, 121 different patterns of equilibration diagram are theoretically possible, but only twenty-five of these are compatible with recovery (regulation), and, of these, only six have been found in operation among the various components and species so far studied. So there are nineteen which may yet turn up. With regard to species differences, it is found that if in any one species the equilibration diagrams for the different components are collected together, they form a pattern which serves to characterize the species. Such physiological characterization of species is no less real than the usual morphological characterization; indeed, it may prove more sensitive in certain instances, and it opens up a new line of thought in comparative physiology.

The most interesting chapter in the book is that on the "Interrelation of Components". Here we study the effect of varying (loading) two or more components at once, and also the effect which loading of one component has on the regulations of other components. Now, the equilibration diagrams of several different components are plotted together on a common set of physiological co-ordinates and we see something quite new—we see the beginnings of a map which would show the integration of the whole animal. This simultaneous handling of different components on one map is perhaps the most important outcome of Prof. Adolph's methods; one has a feeling, for the first time, of getting to grips in a quantitative way with that elusive kernel of physiology—integration. We all know it exists, but now we can begin to measure it, and "science is measurement". Owing to the limited data available only a small field has so far been mapped; but the general picture of integration which emerges is that of a network of interrelated components forming a stress-strain system which is complete in itself. Integration is not some master control superimposed on the observed phenomena; it is just the total map of all the correlations observed. The individual regulations are remarkable enough in themselves, but it is their mutual compatibility which is amazing, and, one may say, the riddle of life.

As already mentioned, in the study of regulations, Prof. Adolph is opposed to any discussion of causation on the ground that it limits inquiry. Many will cross swords with him here, and some may take exception to his somewhat deprecatory references to the "cause-seekers", who must include most present-day physiologists. Cause-seeking he looks upon as the "original sin" of physiologists; it leads to the "accumulation of a body of qualitative facts about which are built up projected or extrapolated aphorisms". He believes that existing data can yield new and significant correlations when handled by his methods, such correlations having hitherto been overlooked simply because observers have, on the whole, only looked for the particular correlations which were suggested by the existing theories. He believes that further knowledge of regulations and integration can best be sought by collecting all the possible data concerning the body and making al the possible correlations, in advance of theoretica speculation.

This point of view, though alien to the classica traditions of physiology, is quite justifiable. There is nothing against it; the only criterion will be —Does it yield worth-while results? It is too soon to say. With regard to the regulation of individua components, nothing very new has emerged; known phenomena have simply been made quantitative but with regard to the interrelation of components and the integration of the whole animal, there does seem to be in his methods the germ of a new and fruitful line of attack. Integration, that most obscure and yet most fundamental aspect of physiology certainly calls for new methods and a new attack; present methods have yielded little and they are for the most part exhausted. A great deal of the quantitative data amassed by physiologists for diverse reasons can be re-examined in the light of regulations and analysed by Prof. Adolph's methods. Many workers will find it possible to apply this analysis to the data of their own researches, and it may lead to a new and probably broader view of their problems.

The book does not make easy reading. It is a difficult subject, of course, but often it seems that an unnecessary obscurity has crept in through too much reliance on abstract terms. The 186 graphic figures are excellent and are a sheet anchor to the persevering reader. The author sums up his work quite fairly as "an attempt to formulate and represent quantitatively many notions relative to regulations that are vaguely and partially present in the minds of all physiologists". O. A. TROWELL.

HISTORY OF CATTLE BREEDING

American Dairy Cattle

Their Past and Future. By E. Parmalee Prentice; with Chapters on Dairy Cattle in America, by Ernest L. Anthony, Lloyd Burlingham, Clifford L. Clevenger, Clifford T. Conklin, Lynn Copeland, Herbert P. Davis, Rockefeller Prentice and Edwin G. Woodward. Pp. xix+453+51 plates. (New York and London: Harper and Brothers, 1942.) 3 dollars.

CLAIMS have been made that certain American breeds of dairy cattle are of immemorial antiquity in their modern form. These claims are set out in herd books, the earliest of which were published in America, and even in publications having the *cachet* of the U.S. Department of Agriculture. History cannot substantiate these claims, and Mr. Parmalee Prentice has successfully demolished them by his careful examination of the evidence and this record of his conclusions.

Since all the cattle in America are descendants of European immigrants, he has been forced to cover a wide field, and, in this connexion, it will be recalled that British breeds of cattle as we know them are of quite recent origin. The first great British breeder was Bakewell (1725–95) and he worked with long-horn cattle, a breed now almost extinct in Britain. What his system was is not known, but it was undoubtedly based upon mating the best with the best in the terms of that day's judgment, and rigorous culling of the offspring that failed to reach the required standard.

From Bakewell's day onwards cattle breeding was in favour among great and wealthy landowners as well as rich tenants of large farms, because the old open-field system had been superseded by enclosed farms, and control of mating was possible. Formerly, as Lord Ernle succinctly puts it, for at least ten centuries "stock breeding, as applied to both cattle and sheep, was the haphazard union of nobody's son with everybody's daughter", and even in the great age of breeding, say 1770–1870, an infinity of crosses was tried. Almost every so-called breed was crossed with almost every other: Devon with Hereford, Hereford with Shorthorn, Shorthorn with anything and everything, Devon with Sussex and so *ad infinitum*. Few, if any, of the British breeds can claim that its contemporary external characters are more than a hundred and fifty years old; most are much less than a century, and the British dairy-breed herd books are more recent still: Jersey 1883, Ayrshire 1878, Guernsey 1885, British Friesian 1912.

It is on the foundation of such facts as these that Mr. Prentice bases his onslaught on the conception of 'pure bred' breeds of cattle. The old principle that 'like begets like' is a fallacy, for brothers and sisters vary widely, and this is no safe rule to breed by. Again, he holds that the mating of high-producing cows to sons of high-producing cows is likely to lead to failure. In place of this system he suggests the use of the Mount Hope index. This implies that the milk and butter-fat must be recorded every year for every daughter and every mate of a given bull, and that the inheritance the bull transmits is found by comparing the average production of all the bull's mates with the average production of all his daughters.

Mr. Prentice's history is stimulating. His criticism of breeding methods is equally so, and his demand that the Mount Hope index, which is based upon performance and not upon type and pedigree, should be used is certainly one that deserves careful consideration; although as Prof. H. G. Robinson has pertinently remarked, "If the bull is regarded as being at least half the herd, the cow shapes the destiny of her own progeny. . . . A good bull deserves good cows."

G. E. FUSSELL.

THE CLIFTON PARK SYSTEM

The Clifton Park System of Farming and Laying Down Land to Grass

A Guide to Landlords, Tenants and Land Legislators. By Robert H. Elliot. Fifth edition. Pp. 261+8 plates. (London: Faber and Faber, Ltd., 1943.) 12*s*. 6*d*. net.

THIS is a new edition of a book long out of print but well known to agriculturists in the early years of the present century. It was no ordinary volume on grassland management, much less a text-book. It was a book with a purpose, namely, to bring to the notice of farmers, landlords, and if possible the administrators, the merits of a certain system of farming as a means of meeting the prevailing agricultural conditions. The interest of the book to present-day readers lies not so much in the detailed methods adopted by Elliot in the field, but rather in light shed on the agricultural problems of the closing years of the nineteenth century and the picture it gives of a man of highly independent mind striving to influence his fellow farmers with rather less than no support from official sources. Indeed the Board of Agriculture and the newly formed agricultural colleges were supporting the "fertilizer and feeding stuff" approach to farming, which in Elliot's view would be largely unnecessary under a rational system of grassland management.

R. H. Elliot, after a period spent as a coffee planter in India, returned to his property at Clifton Park in Roxburghshire and devoted more than thirty years to developing and demonstrating on his farm an alternate husbandry of four-year leys followed by four arable crops for livestock. In this he saw a method of reducing costs, maintaining and improving soil fertility, and increasing the output of the land. This rotation differed from those usually employed at the time in several respects: the grass was left down longer before being ploughed up, the quality of the grass and clover seeds was very much better than was commonly attained at that time, certain species of plants chosen for their deep rooting and drought-resisting habits were included in the seed mixtures.

As a planter and later as a landlord, Elliot was much impressed by the results of soil exhaustion, which he rightly viewed as a matter of the greatest national consequence. He had no faith in artificials as a remedy, and argued eloquently in favour of organic matter coupled with nitrogen derived from legumes as the basis of soil fertility. These could be obtained most cheaply from good grass well stocked, and each time the land was so treated the results improved. As fertility rose the dependence on artificials and concentrated stock foods steadily diminished, as the results of his farming operations showed.

In the course of his work Elliot raised many points of grassland husbandry that called for research for their final solution. This research was not at the time forthcoming. Many of his ideas have stood the test of time; late-flowering red clover, for example, regarded by him as the mainstay of his leys, still maintains its reputation. In his condemnation of rye-grass he was perhaps too sweeping, as improved strains of this grass have abundantly justified themselves on the more fertile soils. His deep-rooting plants on which he counted so much for opening up poor thin soils are not widely included in present-day mixtures, although their good points for certain conditions are admitted. Other pasture plants, notably wild white clover, scarcely mentioned by Elliot, who sowed the ordinary Dutch clover, have had a most profound influence in the productivity of grassland.

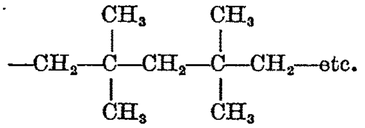
Many of Elliot's proposals which had little support in his time came to pass later. The trade in agricultural seeds has been greatly improved by the Seeds Act 1920 and the resulting activities of the Seed Testing Station at Cambridge. Experimental work on herbage plants and grassland problems has developed in a variety and to an extent that he could not possibly have foreseen, though undoubtedly he would greatly have welcomed them. Agricultural education has left its mark on the farming community, and Elliot's dictum that, "It is well known that, with but few exceptions, agriculturists will not read, and are indeed averse to any form of intellectual exertion" is much less true now than it may have been.

The book gains greatly for modern readers by an excellent preface by Sir George Stapledon, who gives it the necessary orientation in relation to subsequent grassland developments.

STERIC HINDRANCE AND HEATS OF FORMATION

By Dr. A. G. EVANS and Prof. M. POLANYI
University of Manchester

IN the low-temperature polymerization of isobutene by boron fluoride, BF_3, the heat of polymerization, which has been found to be in the neighbourhood of 10 kcal. per mole, is lower than would be expected on the basis of theoretical calculations[1]. Both chemical[1] and X-ray[2] evidence support the head-to-tail chain-structure :

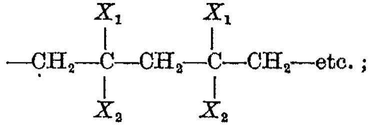


$$-CH_2-\underset{CH_3}{\overset{CH_3}{C}}-CH_2-\underset{CH_3}{\overset{CH_3}{C}}-CH_2-\text{etc.}$$

for poly*iso*butene, but, as has been recently pointed out by Rossini in a private communication to Flory[3], an attempt to build a model of this molecule indicates that there is great steric interference between the methyl groups of successive *iso*butene units. Flory suggests that this steric interference is the reason for the low heat of polymerization of *iso*butene. We have, ourselves, been working for some time on lines suggested by similar considerations of steric hindrance, and, in order to investigate the relation between such hindrance and heats of formation, we have measured the heats of polymerization of *iso*butene, and of the structurally related substances di-*iso*-butene, methyl methacrylate and acrylic acid.

Polymerization of the 1.1 di-substituted ethylene, $CX_1\,X_2 = CH_2$ can lead to a head-to-tail structure :

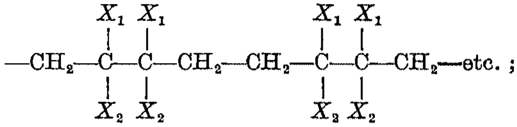
(*a*)



$$-CH_2-\underset{X_2}{\overset{X_1}{C}}-CH_2-\underset{X_2}{\overset{X_1}{C}}-CH_2-\text{etc.};$$

or to a head-to-head, tail-to-tail structure :

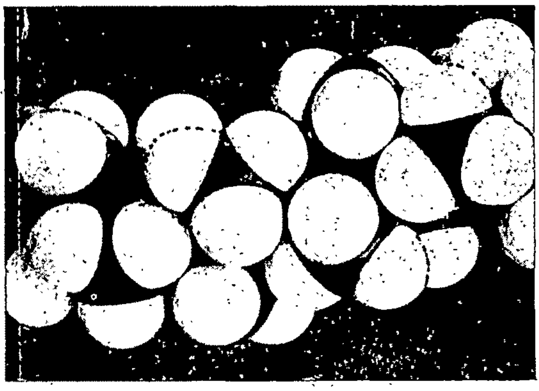
(*b*)



$$-CH_2-\underset{X_2}{\overset{X_1}{C}}-\underset{X_2}{\overset{X_1}{C}}-CH_2-CH_2-\underset{X_2}{\overset{X_1}{C}}-\underset{X_2}{\overset{X_1}{C}}-CH_2-\text{etc.};$$

or to a mixed structure containing both these types. Models of these two structures were built for poly*iso*butene ; that is, when X_1 and X_2 are CH_3 groups.

In the poly*iso*butene molecule of head-to-tail structure (*a*), it was found that the steric interference between the methyl groups was so great that in order to build a model of the molecule, successive *iso*butene units had to be rotated with respect to each other so that the methyl group of one *iso*butene unit fitted in between the two methyl groups of the next *iso*butene unit, as seen in the accompanying photograph of a model. In this way the molecule assumed a spiral configuration, and was found to be quite rigid owing to the close interlocking of the methyl groups. In the Fisher-Stuart models used, the covalent radii of the hydrogen and carbon atoms and the van der Waals radius of the hydrogen atom had their usually assumed values[4]. The van der Waals radius of the carbon atom was 1·35 A. The observed van der Waals radius of carbon is about 1·85 A. in aromatic molecules and 1·7 A. in graphite[4]. Using the rule derived by Pauling[4] that the van der Waals radius is equal to the covalent radius plus 0·8 A. gives a value of 1·57 A. All these values are greater than the van der Waals radius of the model carbon atom used. The extent of the steric hindrance involved in building up the molecule can be realized by the fact that it was only just possible to fit the model together although the van der Waals radius of the carbon atoms was about 0·35 A. less than normal.



Model of poly*iso*butene molecule.

When the poly*iso*butene molecule was built according to the head-to-head, tail-to-tail structure (*b*), it was found that no steric hindrance occurred. Furthermore, when the monomer was a monosubstituted ethylene (that is, X_2 was H) both types of polymer molecule were found to be free from steric hindrance.

Thus, for any 1.1 disubstituted ethylene, we should expect the heat of formation of the head-to-tail polymer of type (*a*) to be less than the normal value owing to steric hindrance. For monosubstituted ethylenes, on the other hand, the heat of formation of both types of polymer should be normal ; and the same should be true in general for 1.2 disubstituted ethylenes.

The heat of formation of a polymer such as polythene or poly*iso*butene can be calculated from rules derived from data of Rossini and Kistiakowsky on the heats of formation and hydrogenation of the lower hydrocarbons. The heats of polymerization of various monomers have been calculated in this way by Flory[5]. These heats of polymerization calculated from data on the lower hydrocarbons, where no steric hindrance exists, refer to polymer molecules which are *ex hypothesi* sterically unstrained. In this way, using the more recent heats of formation obtained by Rossini[6], we have re-calculated the heat of polymerization of gaseous *iso*butene to a sterically unstrained gaseous poly*iso*butene as 21·4 kcal. per mole. If we assume that the latent heat of vaporization per gm. and the heat of solution per gm. are the same for the polymer as for the monomer, then the heat of polymerization of liquid *iso*butene to liquid poly*iso*butene, and the heat of polymerization of *iso*butene in solution, will also be 21·4 kcal. per mole in the absence of steric hindrance.

The heat of formation of liquid poly*iso*butene from the elements has been determined experimentally[7]. From this value and the heat of formation of liquid *iso*butene (as calculated from the heat of formation of *iso*butane[8] and the heat of hydrogenation of *iso*butene[9], and the latent heat of vaporization of *iso*butene), we have calculated the heat of polymerization of liquid *iso*butene to liquid poly*iso*butene as 11·5 kcal. per mole. We have measured the heat of polymerization of *iso*butene in solution. The results gave an average value of 12·8 kcal. per mole. In view of the inaccuracy of the heats of combustion involved in Richardson and Parks' value, the agreement between these two values is sufficient, and justifies our assumption that the heats of solution per gm. of *iso*butene and poly*iso*butene are the same. Both these experimental values for the heat of polymerization of *iso*butene are some 9 kcal. per mole less than the value of 21·4 kcal. which would be expected in the absence of steric hindrance in the polymer.

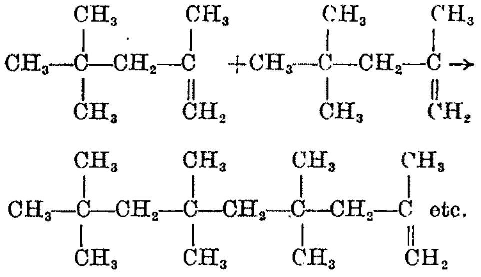
We have calculated the heat of polymerization of gaseous isoprene to a sterically unstrained polymer molecule as 18·7 kcal. per mole. The experimental value for the heat of polymerization has been determined as 17·9 kcal. per mole[10]. The agreement between these two values confirms the expected absence of steric hindrance in the polymer molecule.

For the monomer $CH_3\text{—}CX_1 = CH_2$ we expect the steric hindrance of the polymer of structure (*a*) to be greatly increased when X_1 is changed from CH_3 to C_2H_5. When X_1 is *s*-propyl, *t*-butyl, or neopentyl we expect the large steric hindrance involved to make polymerization impossible. We see a confirmation of this last point in our observation, discussed below, that di-*iso*butene, in which X_1 is neopentyl, forms only a dimer under conditions which lead to polymerization of *iso*butene (the action of boron fluoride at room temperature or lower temperatures).

When X_1 is $COOCH_3$, or C_6H_5 (that is, when the monomer is methyl methacrylate or α-methyl styrene), we expect the steric hindrance of the polymer of structure (*a*) to be of the same order as for poly*iso*butene, where X_1 is CH_3. The fact that the steric hindrance caused by the large groups $COOCH_3$ and C_6H_5 is of the same order as that of CH_3, is because the carbon atoms which join them to the polymer backbone have coplanar and not tetrahedral valencies. This enables the adjacent groups to lie in planes parallel to each other, so that although they are large their mutual interference is of the same order as for CH_3. We have measured the heats of polymerization of methyl methacrylate and acrylic acid and find values of 11·6 kcal. per mole and 18·3 kcal. per mole respectively*. It seems reasonable to attribute the difference to the presence of steric hindrance in the case of the 1.1 disubstituted ethylene, and its absence in the monosubstituted ethylene. This involves the assumption that the polymer of methyl methacrylate is at least predominantly of the head-to-tail type. The theoretical values for the sterically unstrained polymer cannot be calculated in this case.

The smallest molecule in which we would expect steric hindrance to be marked is the nonane $C(CH_3)_3 . CH_2 . C(CH_3)_3$. This molecule has the same structure as a section of the head-to-tail poly*iso*butene molecule. In the nonane $C(CH_3)_3 . C(CH_3)_2 . CH_2 . CH_3$, which is of a head-to-head type, little steric hindrance should be observed. Experimentally, we found signs of steric hindrance reducing the heats of formation in the dimerization of C_8H_{16} to $C_{16}H_{32}$ by boron fluoride. For the heat of this dimerization we find the upper limit of 14 kcal., whereas the value calculated in the absence of steric hindrance would be 20 kcal.

The dimer $C_{16}H_{32}$ was identified as an olefine. This excludes its formation through the intermediate stage of free radicals, since in this case the only possible dimer would be a saturated compound containing a four-membered ring. The mechanism of dimerization, therefore, must consist in the migration of a hydrogen atom from one monomer molecule to the other. If any methyl group would serve equally well for the production of the migrating hydrogen atom, one would expect that the action of boron fluoride on di-*iso*butene would produce some poly*iso*butene thus :

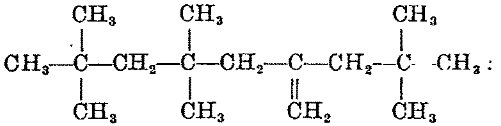


$$CH_3\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_2}{\|}}{\overset{\overset{CH_3}{|}}{C}} + CH_3\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_2}{\|}}{\overset{\overset{CH_3}{|}}{C}} \rightarrow$$

$$CH_3\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_2}{\|}}{\overset{\overset{CH_3}{|}}{C}} \text{ etc.}$$

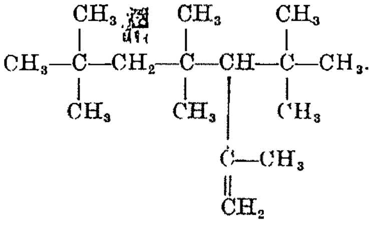
The fact that this does not occur indicates that the terminal methyl groups farthest from the double bond are not active as regards the liberation of hydrogen atoms. The absence of reactivity in these groups is in accordance with the observed behaviour of the methyl groups of a saturated hydrocarbon, as shown by the fact that when a solution of *iso*butene in hexane is treated with boron trifluoride there is no reaction between the *iso*butene and the hexane. It follows that the only active groups in the di-*iso*butene molecule are the methyl and methylene groups attached directly to the double-bond carbon. These groups are active by virtue of the resonance which can occur in the radical $R\text{—}\underset{\underset{CH_2}{\|}}{C}\text{—}\dot{C}H_2$ or the ion $R\text{—}\underset{\underset{CH_2}{\|}}{C}\text{—}\bar{C}H_2$ which is formed by the loss of a hydrogen atom or a proton.

If the migrating hydrogen atom is supplied by the methyl group, then the dimer molecule will have the structure :



$$CH_3\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_2}{\|}}{C}\text{—}CH_2\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_3 ;$$

and if it is supplied by the methylene group the structure of the dimer will be :



$$CH_3\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_2\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}\underset{\underset{\underset{\underset{CH_2}{\|}}{C\text{—}CH_3}}{|}}{CH}\text{—}\underset{\underset{CH_3}{|}}{\overset{\overset{CH_3}{|}}{C}}\text{—}CH_3.$$

Both these compounds are olefines, which show the presence of strong steric hindrance. Further growth by this mechanism would be increasingly difficult sterically and would be accompanied by still further reduced, probably prohibitively small, heats of formation. These are the characteristic features observed in the action of boron fluoride on di-*iso*butene.

If we consider that the polymerization of *iso*butene occurs by the same mechanism as that which we have deduced for di-*iso*butene, we find that the structure of poly*iso*butene must be of the head-to-tail type, in accordance with the evidence quoted earlier on.

---

* We note that Goldfinger, Josefowitz and Mark (*J. Amer. Chem. Soc.*, 65, 1432; 1943) found the value 7·9 kcal. per mole for the heat of polymerization of methyl methacrylate. While we are not in a position to argue the point until the detailed publications can be examined, we believe our value to be correct. In any event, the difference would not affect the argument of this article.

The above considerations would still apply on the assumption that the migrating hydrogen atom came from the $=CH_2$ group, but the eventuality does not seem worth discussion, since such hydrogen atoms are known to be unreactive. as exemplified for the present case by the absence of reaction when ethylene is acted on by boron fluoride.

Our thanks are due to Imperial Chemical Industries, Ltd. (Billingham), for directing our attention to the problem and supplying us with information and material. We also wish to thank Prof. M. G. Evans for important advice on the method of polymerizing methyl methacrylate and acrylic acid, and Mr. J. H. Allen for experimental help.

A detailed account of these experiments will be published after the War.

THE REGIONAL CONCEPT IN GEOGRAPHY

By W. FITZGERALD

University of Manchester

BEFORE the autonomous development of the natural sciences occurred, geography embraced almost all investigations of terrestrial phenomena. This was largely true until the Renaissance and the important voyages of discovery greatly enlarged man's knowledge of the earth's surface. As the sciences took shape in turn it became necessary for geography, in order to retain its identity, to develop its own method, discipline and philosophy and to define the limits of less comprehensive but more specialized investigations. It became, moreover, equally important to state or re-state the relationship of geography to those sciences with which its contacts are closest.

Geographers were slow to adjust their philosophical frontiers to the expansion of science. In the late nineteenth century they had particular difficulty in defining the position of their subject in relation to geology and ethnology, which were reaching full maturity. More recently, meteorology has claimed independent status, and its relation to geography still awaits satisfactory adjustment. The sciences named are those with which geography retains the closest contacts, and between them and geography the boundaries are not always easy to determine.

During the last half-century geographical studies in Britain have undergone a transformation similar to that which occurred in France and Germany at an earlier time. The philosophical evolution of geography has not, however, greatly affected those who would limit the subject to the physical phenomena of the earth's surface and exclude man's adjustment to environment from their terms of reference. The study of land-forms (geomorphology), the atmosphere and the oceans, which comprised the physiography of the late nineteenth century, is the interest of those who claim that scientific geography can go no farthe But much of the geomorphology which passes fo physical geography is concerned with the evolutio of land-forms. As such it is geology. This was mad clear so long ago as 1887 by Prof. J. Geikie when h wrote, "The moment the physical geographer begin to inquire into the origin of any particular physic feature he enters upon the domains of the geologist" The great geomorphologists—Lord Avebury, Arch bald Geikie, Grenville Cole, and others of a recen generation—were geologists primarily, though the secondary interests enabled them to make distin guished contributions to physical geography.

The physical geographer is not required to approac the study of land-forms from the same point of vie as the geologist. He is principally concerned wit the actual geographical location of terrestrial ph nomena and with their spatial relationships withi the regional framework of the world; so that hi statements must be capable of being expressed cartographically. In physical geography, as in all aspect of geography, if the problem cannot be studied b means of maps, particularly by a comparison maps of related distributions, it is questionable the work is legitimate. It is more usual than not fo geomorphologists to exclude man from those agencie which determine landscape. Yet to the geographe the changes wrought by man's occupation of the eart are undeniably important. The deforestation of continental areas, the drainage of marshes and shallo seas, the canalization of rivers, the tunnelling mountain-systems are all features of the physic environment which are as 'natural' as those wrough by geological or climatic agencies—that is, if w accept man as a part of Nature.

A line of argument similar to that used in definin the relations of geology and geography may be followed in tracing the relation of physical geograph on its climatic side, to meteorology. The physic of the atmosphere is not a branch of geography, an a meteorologist undertakes his researches withou necessarily possessing a geographical outlook. Th climatic geographer is particularly interested in th zonal or regional arrangement and distribution climates; whereas the geographer (without prefix), i addition to this, undertakes the investigation of th relation of climate—as one aspect of physical environment—to the life of mankind, the setting of th inquiry being, as always in geography, an areal uni or region.

To the geographer the pattern in which phenomen are arranged within an area is a matter of primar importance. He is concerned not only with thei spatial relationships, but also with their interaction as, for example, the effect of climate on the characteristics of vegetation. The geographical patter changes, usually by a graded transition rather tha abruptly, from one area to another, and grants distinctive character—a 'personality'—to the unit area called the 'region'. As the region is a concept its frontiers are fixed not by Nature but by th geographer, and there may not always be agreemen among geographers regarding either the regiona boundaries or the criteria on which the delimitatio of the region is based. Regions provide a framewor which is convenient and, indeed, necessary for th systematic investigation of the environment of man Without such a regional plan of the world as an instrument, systematic geographical investigation is no possible. There is, unfortunately, the necessity t employ the term 'region' for every unit of are irrespective of its magnitude, as the English language is deficient in words which signify regions of different dimensions. Attempts to coin regional terms, comparable to 'pays' of the French, have, unfortunately, failed to obtain general recognition from the main body of geographers.

The division of the world into political units is scientifically unsatisfactory to the geographer, because the criteria on which it is based bear no necessary relation to geographical reality; and largely because of the inadequacy of States as geographical units the idea of the 'natural region' has been introduced. Its theory is to group together geographically the factors of environment within a scientifically acceptable framework in order the better to investigate their spatial relationships. A comparison of the historian's and the geographer's methods may help to clarify the purpose of regional division. The historian, confronted with the investigation of all history, prepares a chronological system of periods, according to criteria the relative importance of which he alone is able to determine. Only by such a division of time is he enabled to undertake the detailed investigations which are essential to the standards of historical scholarship.

The theory of natural regions was introduced to geographical thought in Great Britain by Herbertson of Oxford at the beginning of this century. The validity of the system which he devised is still widely acknowledged, though there have been alternative systems, notably those of Continental geographers. To Herbertson climate was the factor of environment which exerted the greatest influence on man; and for him it was the principal criterion of regional division. There is a considerable measure of agreement regarding the indirect influence of climate on civilization through the medium of its control of earth-sculpture, soil characteristics and vegetation, though there is objection to a theory of the climatic control of human life. Other, but subsidiary, criteria introduced by Herbertson to his regional division of the world included both orography and situation with reference to land and sea, but in the last analysis his regions are of climate. As such they comprise merely one category of natural region with which may be compared regions of vegetation and geomorphological regions, which are equally 'natural'.

All such systems agree in their limitation of the term 'natural' to phenomena which are external to man and unaffected by his activities. In recent time, however, certain geographers have claimed for man, as the architect of the cultural landscape, a place in a system of natural regions. To them the cultivated soil, for example, is a phenomenon as 'natural' as the primeval forest. The introduction of man as an agent of geography greatly complicates the attempt to reach an agreed basis of regional division. Nevertheless, it demands attention, more particularly because of its service in bringing together in fruitful relationship the physical geographer and the geographer of humanistic interests.

The wide divergence of interests between geographers in Great Britain would probably not have arisen if the subject had been consolidated at the time when geology and ethnology were completing their separation from it. For such a task a man of scientific and philosophical equipment equal to Alexander von Humboldt or Carl Ritter was required; and it is regrettable that there was no such British geographer in the nineteenth century to prepare the foundations. The backwardness of geographical investigations in Britain during that century, in contrast to the great activity in France and Germany, demands an explanation, but for our present purpose it is sufficient to indicate that geography in Britain suffered from both lack of discipline and uncertainty of objective in the early stages of its active growth.

When physical geography is re-orientated, with the regional concept at its centre, as already proposed, a considerable advance will have been made towards the elimination of the dualism which now permits the physical geographer and the geographer of humanistic interests to follow divergent courses. The unification of the subject would be assisted by the abandonment of the term 'human geography' which has only recently come into currency. It is widely misunderstood, as well it might be, for it is a mistranslation of 'la géographie humaine' which cannot be so literally rendered in English.[1] The aspects of geography which it comprises are social, economic and political, and as prefixes to 'geography' these adjectives are sufficient. (The legitimacy of 'racial geography' is more doubtful, and will be mentioned later.)

The unification of geography depends, however, on more than the elimination of an unsatisfactory yet widely used term. It proceeds from the recognition by the geographer of humanistic interests—whether social, economic or political—that, like the physical geographer, he is concerned with the spatial relationships of certain phenomena which are involved in the life of man within a region, or series of regions. He investigates the geographical record of man's activities in economic, social and political affairs, but his unit of study, it cannot be too strongly insisted, is the place or region.

The place of man in geography offers the greatest of all practical difficulties in the systematization of the unified subject. Man is studied from different points of view in a number of other sciences, including physical and social anthropology, with which ethnology is so closely akin as to be almost synonymous, and archæology. To the geographer man is interesting because (1) in his settlement and other activities he responds to the opportunities which his environment offers, and (2) in his response to the conditions of environment he alters the characteristics and the spatial arrangement of the phenomena which constitute the environment.

The distribution of the human population over the world is undoubtedly of legitimate interest to the geographer. How that distribution has come about, the effect it has on the pattern of phenomena within a region, and the influences which are at work to alter the distribution—these are topics which the geographer studies without challenge. In regard to the somatic characters of man, only the anthropologist speaks with authority. There are undoubted racial differences between the populations of different zones, but the description of those differences in their relation, if any, to environment might well be left to the anthropologist or ethnologist, until the causes of racial differentiation between one community and another have been much more thoroughly investigated.

The argument of this article is, in effect, a recommendation of the regional method in the study of geography. It is, indeed, more, for it suggests that there is no alternative method of approach. The geographer's unit is the region, and only by reference to it does he make his distinctive contribution.

TAXONOMY OF THE MOTHS INFESTING STORED FOOD PRODUCTS

By DR. A. STEVEN CORBET
British Museum (Natural History)

UNTIL about a quarter of a century ago, the identification of butterflies and moths was effected, almost entirely, by comparing their wing- and body-colour patterns with named material in collections or with published figures and descriptions. Inevitably, differences of opinion arose, which could not be resolved on morphological evidence, between collectors who knew the insects alive and systematists who studied them dead. The prolonged controversy about the conspecificity or otherwise of the Pierid butterflies *Catopsilia crocale* (Cramer) and *C. pomona* (Fabricius) in the Oriental region is a case in point[1].

Although it is more than a century ago since Rambur[2] showed that the male genital organs were a satisfactory criterion for separating the superficially very similar species of butterflies in the group allied to the British 'grizzled skipper', *Pyrgus malvæ* (Linnæus), it is only within the last forty years or so that other investigators, such as Rothschild and Jordan, Chapman, and Pierce, began to investigate the genitalia of certain lepidopterous groups in which they were interested. The male genitalia—or, more precisely, the male external genitalia—consist of an assemblage of paired and median structures, usually heavily chitinized, that come into operation during the act of copulation. It became evident that, while not entirely immune from variation, the characteristics of these organs were much less subject to modification than were those of the colour pattern and other characters previously used for specific discrimination. In the majority of cases the specific features of the male genitalia were found to remain practically constant throughout whole series of insular geographical races, even among species where the wing patterns of some of the constituent races were quite dissimilar.

In practice, most attention has been paid to the characteristics of the genitalia of the male, which are more complex than those of the female, and so have greater potentialities for displaying differences in shape and size of the constituent parts. The simpler female external genitalia appear to show fewer specific differences and, in point of fact, seldom show any among closely related species when the genitalia of the corresponding males are devoid of specific distinctions.

The use of the genitalia to prove the conspecificity of geographical races showing markedly different superficial characters has been mentioned above. The converse situation occurs in which the uniformity of superficial characters of colour pattern, etc., point to the conspecificity of specimens from a wide geographical range, while the genital characters separate them into a series of distinct groups corresponding to different geographical localities. Thus, in a remarkable case known to me[3], the Lycænid butterfly *Pratapa anysis* (Hewitson) shows no marked differences in its superficial characters throughout its range from Nepal, through Burma and Malaysia, to the Celebes, but, on the basis of the male genitalia, the specimens fall into clearly differentiated groups which correspond exactly with the geographical subregious found in the range of the species. It may be added that these differences are of a degree found elsewhere in the genus only between distinct species.

The examination of the genitalia is not a universal panacea for problems in the taxonomy of the Lepidoptera. There are cases, particularly among the Pierid and Danaid butterflies, where related but undoubtedly distinct species have the genitalia structurally indistinguishable. However, even after allowance has been made for these exceptions, the fact remains that the genitalia afford the most reliable means of specific discrimination for the vast majority of the Lepidoptera.

With the moths, progress has lagged far behind that with the butterflies. A notable contribution has been the work of Pierce[4] and his collaborators, who have figured the male and female genitalia of all the British species of Lepidoptera with the exception of the minute leaf-mining Nepticulidæ. The European species of this latter family have been similarly investigated by Petersen[5]. Only in the family Sphingidæ ('hawk moths') have the male genitalia of the species of the whole world been comprehensively studied and figured (Rothschild and Jordan[6]).

Almost always, the examination of a group on the basis of the genital structures results in an increase in the number of recognized species, many former species being revealed as 'species-complexes' consisting of an assemblage of species distinct in respect of their genitalic characteristics, but possessing the same general facies as regards colour pattern, etc. There are a few instances where examination of the genitalia has led to a reduction in the number of species recognized; thus, in the Danaid genus Euploea Fabricius of the Indo-Australian and African regions, the number of listed species has been cut to a third of its former dimensions.

This systematic technique—the examination of the characteristics of the external genitalia—is not a tool reserved for those interested in the speciation and distribution of the larger and more conspicuous Lepidoptera. It is available for application to the smaller species of moths which directly affect the affairs of mankind and hence are of immediate concern to the economic entomologist. Without accurate knowledge as to the specific status of the material which is the subject of experimental work, research in quest of methods of eliminating or controlling these noxious moths will rest on a flimsy foundation. While results obtained by an empirical or semi-empirical process may lead to successful methods of control in some cases, it is only possible to bring research to full fruition and to marshal all the potentialities of the discoveries made if the data used for the identification of the species is based on careful systematic work employing an up-to-date technique.

The War has served to throw emphasis on moths the larvæ of which infest stored food products, and it became apparent that our knowledge of the systematics of these insects was very far from complete. A reinvestigation of the taxonomy of the species of moths involved was initiated, therefore, by the Department of Entomology at the British Museum (Natural History) and was carried out by me, in collaboration with W. H. T. Tams. The full results of this investigation are in course of publication[7], although the main discoveries made in respect of the commoner moths have been incorporated in a pamphlet in the Economic Series issued by the Museum[8].

Of these moths of economic importance, only the

Pyralid genera Ephestia Guenée and Plodia Guenée had been worked out satisfactorily[9], but, even in this group, it has recently transpired that one of the commoner species is, in fact, a species-complex. In other groups, the work carried out at the British Museum has shown that, as was expected, yet other species-complexes are present. This is the position with such well-known insects as the 'large tabby moth', *Aglossa pinguinalis* (Linnæus); the 'honey moth', *Achroia grisella* Fabricius; the 'corn moth', *Tinæa granella* (Linnæus); and the 'white-tip clothes moth', *Trichophaga tapetzella* (Linnæus), and it is highly probable that, were more adequate material available for study, the position of other species would be found to be similarly complicated. In some of these species-complexes, the two or more closely related species fly together, whereas in others it would seem that the overlap in the distribution is of a comparatively recent date; the latter may constitute examples of geographical races becoming established as separate species. In the British Museum there is a paucity of material from America; but the impression has been gained that the apparently similar New World forms are by no means always so closely related to the Old World species as is generally supposed.

Often the differences in the genitalia between these closely allied species are small although constant, but, judging by the position in groups of which a sufficiency of specimens is available, it is usually possible to correlate some distinctive features in the wing pattern with these differences in the genitalia. With certain species, at present, an examination of the male genitalia is the only certain means of identification, particularly with rubbed specimens which often constitute the material available.

The important question arises as to whether the species of moths in these species-complexes, which differ constantly almost only in the genitalia, exhibit differences among themselves in the earlier stages, and in the larval food and habits. As yet, we have little exact information on this subject; but it may be remarked that, of the four closely allied species in the *Tinæa granella* complex, although *T. granella* (L.), *T. infimella* Herrich-Schäffer and *T. cloacella* Haworth are so similar in wing pattern that identification of a single specimen may be impossible without recourse to examination of the genitalia, only the larvæ of *T. granella* and *T. infimella* have been found infesting grain, although all three species, together with the quite similar *T. ruricolella* Stainton, are known to utilize certain species of fungi as the larval food material. Moreover, it appears that *T. granella* prefers wheat, while *T. infimella* favours rye: although this latter species is a pest of stored wheat in Scandinavia, it has not yet been found infesting grain in Britain. A dissimilarity in larval behaviour is found in the two rather similar species of *Ephestia*, *E. sericarium* Scott (= *kühniella* Zeller), well known as the 'Mediterranean flour moth' or 'mill moth', and *E. elutella* (Hübner), the 'cacao moth'. The mill moth is a notorious pest in flour mills throughout the world, the larva feeding on flour at all stages in the milling process and constructing webbing which eventually impedes the operation of the machinery to such an extent that fumigation of the mill is necessary. On the other hand, the larva of *E. elutella* attacks the whole wheat grain, but shows a partiality for the germ: this species is also a well-known pest of other food products such as dried fruit, cacao beans, etc.

Much work remains to be carried out in this field of economic entomology, but it is clearly essential that the taxonomic studies should first be completed. It is a waste of time to attempt to investigate the life-histories and habits of living material consisting of a complex of unresolved species. Although the work at the British Museum has placed the systematics of the food products moths on a reasonably firm foundation, there are still a few threads to be unravelled, and, doubtless, quite a host of names remains to be added to the lists of synonyms.

It may be added as a matter of interest that recent work on the chætotaxy of the lepidopterous larvæ infesting stored food products carried out at the British Museum by Dr. H. E. Hinton[10] has shown that, with a number of species, identification of the larvæ is easier and more certain than is the case with the adult moths.

OBITUARIES

Prof. Isidor Traube

THE death of Isidor Traube at Edinburgh at the age of eighty-three brought to a close a life of great significance to present-day exponents of physical and colloid chemistry. Born at Hildesheim of Jewish parents (his father was a merchant), Traube entered the University of Berlin in 1879, where he studied chemistry under A. W. Hofmann and physics under Helmholtz. Later he worked in the physiological institute of Du Bois Reymond, and was awarded his doctorate for a thesis in the field of organic chemistry. After a period of military service, which appears to have been little to his liking, he became for a period assistant to Bernthsen. Contact with Bunsen and Hermann Kopp turned his thoughts to the then embryonic science of physical chemistry and in particular to the phenomena of solution, adhesion and cohesion, to the study of which so much of his life was later to be devoted.

Greatly impressed by the experimental results of Raoult, Traube's speculative mind early recognized the relation between the gas laws and Raoult's empirical laws relating to dilute solutions; he was aware also of the implications regarding the dissociation of the electrolytes to which many of Raoult's data referred. Unfortunately for Traube, instead of publishing his interpretations of these results (his paper would have anticipated van't Hoff by two years), he communicated them (1884) to Lothar Meyer, then professor of chemistry at Tübingen. Meyer, unimpressed by the accuracy of the Frenchman's data, which in his opinion required further substantiation, cautioned the young Traube against hasty publication. The papers of van't Hoff and Arrhenius were published in 1886–87.

After a short interval in Heidelberg, Traube migrated to Bonn, where he worked as assistant at the Agricultural Academy. It was there that he began his studies of the viscosities and surface tensions of liquids. So early as 1891 he expressed the opinion that the molecules forming adsorbed films at the surfaces of solutions obey equations of state analogous to those of three-dimensional gases, the area per molecule being the analogue of the molecular volume, and the lowering of surface tension that of the gaseous pressure. This time Traube anticipated the march of scientific opinion not by two but more nearly by thirty years, for it was not until the impetus given to the study of surface phenomena by Hardy, Langmuir and Harkins had made itself felt that the correctness of his view was firmly established by Adam (1921), Volmer (1925) and others.

Already in 1885 Traube had shown that with members of a homologous series dissolved in water (for example, the lower alcohols or the alkyl acetates) equal lowerings of the surface tension of the water were produced by concentrations which decreased *geometrically* about three-fold for each additional CH_2. In much later work he extended a form of this generalization (Traube's rule) to adsorption at liquid/liquid and solid/gas interfaces, although he was careful in this last case not to confuse the affinity or free energy of adsorption, to which the rule would apply, with the saturation capacities of the surface, to which it would not.

Traube found a practical outlet for these discoveries in the assessment of the fusel oil contents of spiritous liquors. He also applied his theories of film formation and surface activity to explain the viability of drugs in living tissues (1904). Ever since its formulation, Traube's theory of drug action has exercised a profound influence on pharmacological research, and perhaps to-day more than holds its own against the rival lipoid solubility hypothesis of Overton and Meyer. Traube's other studies included such diverse subjects as the molecular volumes and intrinsic pressures of pure liquids (1895–1920), the theory of critical phenomena (1902), colloidal gold, the theory of catalysis (1913), the stability of matter in the submicronic state of division (1928–29) and the froth flotation of minerals and of organic chemicals.

A careful experimenter and possessing an exceptionally penetrating mind, Traube was never over-elaborate either in his laboratory techniques or in his formulation of theories. Unlike those of his great contemporaries, Nernst and Ostwald, his writings were never pontifical, and, so far from their becoming current dogma, it was left to later generations of chemists to appreciate their essential merit.

After holding for a third of a century the title of 'extraordinary' professor at the Technische Hochschule, Berlin, Traube came as an *émigré* to Britain in 1934. He settled in Edinburgh, where he was welcomed as a guest of the University. Active-minded to the last, he completed shortly before he died the manuscript of a book of reminiscences. To this and to his surviving daughter, Dr. S. Boas-Traube, I am indebted for the biographical details given in this note. D. H. BANGHAM.

WE regret to announce the following deaths:

Mr. J. S. Addison, deputy chairman of Courtaulds, Ltd., and chairman of the scientific advisory committee of the Empire Cotton Growing Association, on December 15.

Mr. Edward A. Martin, formerly secretary of the South-Eastern Union of Scientific Societies, on December 14.

Mr. H. F. Witherby, M.B.E., the well-known ornithologist and publisher of works on natural history, on December 11, aged seventy-three.

NEWS and VIEWS

A Programme for Reconstruction

THE statement, "Forward—By the Right", issued by the Tory Reform Committee (Pp. 16. Tory Reform Committee, House of Commons, London, S.W.1), is of considerable interest to scientific workers as indicating principles and objectives on which there is a large measure of general agreement, however widely opinions may differ as to the measures by which the objectives are to be attained. Eight principles are enunciated and illustrated: national unity; empire unity; the interdependence of nations; the full development of resources; the practical approach; individual freedom; trusting the people; and finally, that of first things first. Much general support will be found for the view that in Imperial affairs attention should be transferred from abstract questions of political status to such practical problems as Imperial defence, air and sea transport, broadcasting and communications, education, research, economic development and migration. In regard to the interdependence of nations, it is urged first that those military organizations for consultation and joint action which exist between the United Nations should be maintained, and also those organizations such as the Middle East Supply Centre which could be adapted to the needs of peace and assist in removing the causes of dispute. The International Labour Office and the Hague Court should be revived and such joint enterprises as are exemplified in the Hot Springs Conference developed. While mutual co-operation and understanding between the British Commonwealth, the U.S.A., the U.S.S.R. and China must form the basis for establishing a framework of stability, the final framework of any world organization will require a broad foundation.

Under the development of resources, the Statement, after emphasizing the necessity of a policy of full employment, including Empire development, agriculture and the development of exports, calls for the devotion of far greater resources in men and money to scientific and technical research, including provision in the educational system of Great Britain for the increased numbers of trained scientific workers required. On the question of planning, the Statement is not clear, but it emphasizes the necessity both of ample statistical and other information as a basis, as well as ensuring that the objectives of policy command general support. Dealing with public control, it is advocated that the public interest should be the decisive test; private profit is not accepted as the sole test of public advantage. The peacetime essentials are regarded as, first, the retention of adequate armaments and compulsory military training; secondly, full employment as a condition of individual self-respect and independence, and as a guarantee that the maximum effort is being harnessed to the national objectives; thirdly, the provision of homes for all of an adequate standard; fourthly, the establishment of an educational system which will enable any child to develop his capacities and character to the full; and fifthly, social security guaranteed by adequate minimum wages and a system of social insurance on the lines proposed by Sir William Beveridge.

Transport Problems in Reconstruction

SUPPLEMENTING two earlier broadsheets, Nos. 202 and 207, on "Retail Distribution and Town Planning" and on "Space for Leisure", respectively, Political and Economic Planning has now issued a further broadsheet in its attempt to analyse the needs of the consumer which physical planning should satisfy. This broadsheet, "Use and Misuse of Transport" (No. 211), reviewing first the general problems of pre-war transport in Great Britain, including the mounting delays, excessive journeys, travelling to work and the consequent loss of time, points out that if the full social costs are taken into consideration, the value of a great proportion of the transport which has been considered as normal is not commensurate with the price paid for it in money, time, energy, ill-health and loss of amenity. The position could not have been allowed to drift for many years longer without a real crisis developing. Dealing first with the comparatively limited question of reducing pressure on the roads, the broadsheet emphasizes that if travel by public vehicles in place of private car or vehicles is to be encouraged, accessibility is the key to the whole problem. More parking space and legal recognition of joint ownership of a car, the development of retail delivery services, and the utilization of any possibilities of underground travel as well as travel by air, are suggested; and the broadsheet gives a warning against allowing ourselves to be left behind in utilizing the air, as we were by the rapid development of the internal combustion engine.

The major possibilities, however, lie in the reduction of the demand for transport. The wider utilization of piped services and of the telephone in eliminating journeys is obvious, but the decentralization of services and amenities so as to rectify serious mistakes originally made in housing estates is also important. The major problem is that of reducing the journey to work, but there are limits to the alleviation which local employment can provide in this respect, and the broadsheet analyses closely the possibilities which zoning offers, particularly in regard to segregating traffic. Six different types of zone are enumerated, and discussing their interrelation, the broadsheet suggests that industry, warehouses and wholesale markets should be placed on the outskirts of a town; living quarters, offices, shops and schools would then be kept free from the intrusion of heavy traffic. Recent plans for large towns have shown a tendency in this direction. Such zoning, however, leads to the question whether synthesis is possible between the principles of the neighbourhood unit in which people's lives are localized, and of zoning, which is recommended for reasons of economic efficiency, of amenity and of a rational arrangement of transport. The problem of securing employment for people near their homes is more intricate than the decentralization of services and leisure facilities. While it is important that the light mobile industries should account for a much higher proportion of total employment, the issues cannot be decided purely from the point of view of transport, and a broad approach to this very broad problem is essential, as well as vision and boldness.

Association of Scientific Workers of Southern Africa

THE success achieved by the Association of Scientific Workers in Britain, the United States, and Australia, has inspired the establishment of a similar Association recently in South Africa, under the title of the Association of Scientific Workers of Southern Africa. Various problems such as the recent and still incomplete industrialization of the country, the widely scattered population, and the great distances between the few considerable urban and industrial centres, have necessitated an approach to problems of organization and policy differing a good deal from those adopted in Britain to achieve the same fundamental aims of promoting the application of science and the scientific method to the welfare of mankind, while at the same time furthering the professional interests of scientific workers. Also, the statutory position of a trade union is quite different in South Africa from that in Britain.

The establishment of the Association in South Africa met with a good response. The two branches, Johannesburg and Cape Town, now have a joint membership from all parts of the Union and the Rhodesias of more than 350. Public conferences have been arranged and have attracted considerable attention. Memoranda have been presented to the Government Health Services Commission, and the Social and Economic Planning Council, and for publication, on various problems concerning the application of science to national problems. Recently the Association co-operated with the Medical Council in the matter of registration of laboratory technologists, who now form a large and enthusiastic group within the Association. The Association is also at work through special sub-committees, on war emergency problems, education, research, finance and organization, and similar problems. It is expected that further branches will be established in the near future. The chairmen and addresses of the two existing branches are P. S. Malan, P.O. Box 1065, Cape Town, and Rena G. Knight, P.O. Box 8083, Johannesburg.

Scientific Film Association

THE Scientific Film Association was formally constituted at an extraordinary general meeting held on November 20. The primary aim of the new Association is to promote the national and international use of the scientific film in order to achieve the widest possible understanding and appreciation of scientific method and outlook, especially in relation to social progress. It will also collect, collate and distribute information on the scientific film, and publish comprehensive lists of films graded according to scientific merit and suitability for audiences. The Association hopes to establish relations with Government departments, public bodies and other organizations which are in a position to make, use or circulate scientific films; and it is also proposed to organize a representative panel of men of science to advise producers of films of all types on scientific matters in connexion with such films and to maintain close contact with the film industry. All inquiries should be made to M. Michaelis (honorary secretary), 51 Fitzjohn's Avenue, London, N.W.3.

Prehistory in the Deccan

So long ago as 1930, in the September number of *Antiquity*, Mr. M. C. Burkitt made an attempt to set out in some order the early archæological discoveries of south-east India. The bases for the study were the finds and notes made during a long period of years by Mr. L. A. Cammiade over a wide area of country including the districts along the lower reaches of the Godavari River. Actually, the finds made near this river were all from the surface and could not be accurately dated. They were, however, mostly microlithic in character; but it was clear that many ages were represented. Mr. H. D. Sankalia has now published a short article, "Studies in Prehistory of the Deccan (Maharashtra): a Survey of the Godavari and the Kadva near Niphad" (*Bull. Deccan Coll. Res. Inst.*, **4**, No. 3) which, while not taking us much further, has a certain interest. Briefly, the Godavari has, in places, cut down through the trap to a low level, having previously deposited on the trap a series of gravels in which Mr. Sankalia has discovered a few artefacts *in situ*. Unfortunately, the illustrations are not very good, and it does not appear that any outstanding finds have been made, but Mr. Sankalia is to be congratulated on having started an investigation which eventually may prove to be of considerable interest. It must always be remembered that the well-known micro-industries of the rock shelters in the Central Provinces of India, far from corresponding to the Mesolithic industries of Britain, are apparently for the most part post-Christian in date. At the same time there are post-Middle Stone Age finds of small implements in the Cammiade collection which probably do date to Late Pleistocene times. Further work by Mr. Sankalia may help to elucidate these problems.

St. John's Wort in Australia

St. John's wort (*Hypericum perforatum* var. *angustifolium*), introduced into Australia in about 1880 as a garden plant, is now a serious weed in many parts of that country. Besides reducing the carrying capacity of the pasture, stock may become affected with 'wort dermatitis', for the hypericin in the plant acts on the nervous system, rendering the exposed non-pigmented areas of their skin photosensitive. Control measures of various kinds are being tried, including improvement of the pasture by sowing competitive species, chemical treatment and the liberation of insect parasites. Some account of the success attending these trials is given in recent publications of the Australian Council for Scientific and Industrial Research. Bulletin 151 consists of a paper by R. M. Moore and A. B. Cashmore, who have investigated the problem from the agrostologist's point of view, while the entomological aspect is specially dealt with by F. Wilson and T. G. Campbell in the Council's *Journal* (**16**, p. 45). The results are most promising. Subterranean clover (*Trifolium subterranean*), a winter-growing annual, proved an efficient competitor with St. John's wort, and in association with perennial grasses, such as *Phalaris tuberosa* or *Lolium perenne*, almost completely eradicated the weed and provided a productive and nutritious pasture. The mixture is best sown with a dressing of superphosphate after a summer fallow, a dense pasture being afterwards maintained by regular top-dressings and a rotational system of grazing. The use of dark-coloured stock is also recommended as they are less prone to wort dermatitis. For entomological control, three insects have been established in Australia, two leaf-eaters, *Chrysolina hyperici* and *C. gemellata*, and a root-boring Buprestid, *Agrilus hyperici*. The prospects of success are good, particularly with Agrilus, as it is remarkably free from predators and parasites, but the Chrysolina species have a high reproductive rate, and judging from experience in France, all three insects can play a useful part in the control of the weed.

Stellar Spectrophotometry in the U.S.S.R.

Two recent publications (*Bull. Acad. Sci. Georgian S.S.R.*, **3**, No. 6, p. 509; No. 7, p. 657; 1942) give news that astrophysics still flourishes just beyond the high-water mark of the German advance into southern Russia. At Abastumani Observatory an extensive programme of photo-electric colorimetry of $B8$–$B9$ stars was begun in the summer of 1940 and is still in progress. The colours of all stars of these spectral types brighter than 7·5 mag., lying in a zone within 20° of the galactic equator, are being measured with an antimony-cæsium photo-cell attached to a 33 cm. reflector. Colour filters give effective wavelengths of 4060 A. and 5280 A., the resulting colour equivalents being on a base-line slightly longer than ordinary photographically determined colour indexes. The greater sensitivity, range and stability of the antimony-cæsium cell enables the Russian observers, V. Nikonov and E. Brodskaja, to obtain observations of which the probable error is less than $\pm 0{\cdot}01$ mag. for stars brighter than the sixth magnitude, and less than $\pm 0{\cdot}02$ mag. for the fainter stars. When full results of this programme are available, they should add greatly to our knowledge of the selective absorption of light by interstellar matter situated fairly close to the sun.

Meanwhile, a vexed point regarding the colour temperature of α^2 CVen is being investigated at Mt. Kanobili. Thirty-three observations of the star taken in the spring and summer of 1941 show a maximum variation of colour temperature of 2,000°, which agrees better with the spectrum changes than the value of 10,000° found by Tai (*Mon. Not. Roy. Astro. Soc.*, **100**, 94; 1939). A puzzling feature of the observations is that the star is bluer at minimum than at maximum, a characteristic which differentiates it sharply from such intrinsic variables as Cepheids and long-period variables. Observations are being continued at Abastumani in happier circumstances than any obtaining since the inception of the programme.

South African Institute for Medical Research

The annual report for 1942 of the South African Institute for Medical Research in Johannesburg indicates that this progressive Institute is playing its full part in the war effort. Staffed by 153 Europeans and 118 Africans, its activities are wide. In 1942, its buildings, which were no longer adequate to the large demands for serum for civilians and for army needs, were enlarged; a branch laboratory was established at Bloemfontein. The erection of a large plant for the manufacture of dried human and other serum was made possible by a grant of £10,000 from Sir Ernest Oppenheimer and the Anglo-American Corporation of South Africa. The production of vaccines and sera for the troops has been very greatly increased; staff are being trained for the administration of military hospitals and for their laboratories, and two mobile laboratories and nineteen military hospital laboratories have been established in the Union. Special military medical problems are being investigated. Other war activities of the Institute include vitamin assays, food analyses for military needs, the production of anti-gas-gangrene serum, the study of insect vectors of disease, plague, relapsing fever, typhus and yellow fever. The list of other researches being done is impressive, and the Institute's routine diagnostic work is evidently one of its most important activities.

Rapid Disappearance of Smallpox

According to the May issue of the *Statistical Bulletin*, the organ of the Metropolitan Life Insurance Company of New York, in 1942 for the first time in the history of the United States the number of smallpox cases fell below 1,000. Eleven States were entirely free from the disease, and three other States reported only one case each. Texas alone had more than 100 cases. During the whole year there were less than ten smallpox deaths. In Canada there were only six cases and no deaths. The 897 cases of smallpox reported in the United States in 1942 showed a marked decline from the previous low record of 1,446 cases in 1941 and were only a fraction of the number for 1940, 1939 and 1938, when the cases numbered 2,797, 9,877 and 14,977 respectively. In an outbreak of 65 cases in Pennsylvania, the patients had either not been vaccinated or had long outlived their immunity. Apart from 13 unvaccinated school-children, the victims were past middle age.

Production of Rubber in Europe

A short notice of an article in *Agricultura* (128, Dec. 1942) entitled "La producción de caucho en Europa" appears in the *Revista De Formacion Y Documentacion Profesional* (No. 7; 1943). It is pointed out that in the Mediterranean basin it is possible to cultivate plants from which a secretion having the characteristics of rubber has been extracted. This question attained great importance after the occupation of the Ukraine by the enemy, because large tracts there were devoted to the cultivation of *koksagyz*, a dandelion-like plant, from which it is claimed that fairly satisfactory rubber could be obtained; the percentage of rubber from the extract was as high as 27. The article suggests that, if to this are added the species which can be cultivated in the Mediterranean basin, and also the synthetic rubber manufactured by the Germans at the Buna works, a possible solution of the natural rubber supply for European countries would be forthcoming.

Maintenance Work in Electrical Supply

A paper on "Maintenance of Distribution Plant and Mains on A.C. Networks" was read before the Institution of Electrical Engineers in London on November 10 by Messrs. F. N. Beaumont and F. A. Geary. They stated that the frequency with which apparatus should be examined, and the time to be allocated for each overhaul, are dependent on (*a*) the design of the individual unit in relation to its electrical duties and the atmospheric conditions under which it has to operate; (*b*) the electrical and mechanical strength of the materials employed; (*c*) the accessibility of the parts requiring normal inspection and testing; and (*d*) the physical lay-out and housing of the units, together with the facilities available for carrying out routine maintenance on site. The closest co-operation between the designer and the maintenance engineer is at all times desirable, in order that those details in design which require excessive maintenance may be suitably modified. It is the function of a maintenance engineer to organize the necessary maintenance, examination and testing of all sections of plant under his control, so that the plant may carry out its functional operation successfully and incipient faults be found and eradicated before they lead to failure on the line. The aspects and items of equipment dealt with in the paper are as follows. Staffing, safety precautions, record systems of plant maintenance, switchgear maintenance, batteries, transformers, transformer chambers, fire-fighting installations, protective gear and mains. The paper shows that maintenance, combined with adequate records, can foster improved design, to the mutual advantage of manufacturer and user, in order to obtain for future purposes the best design and lay-out practicable.

Electricity in Mines

A review of this subject given (*J. Inst. Elect. Eng.*, 90, Pt. 1, No. 34; October 1943) by Mr. J. A. B. Horsley covers the use of electricity in mines under the Coal Mines Acts which are operative in Great Britain. The review gives certain statistical data and surveys technical developments, British Standard specifications, effect of recent legislation, and future developments.

Literature of Penicillin and Similar Substances

Last September the National Research Council of Canada issued "Abstracts on Penicillin and other Antibiotic Substances" (National Research Council, Ottawa: No. 1160. 1.00 dollar). Compiled by Miss Muriel E. Whalley, of the Research Plans and Publications Section, it arranges by authors 185 abstracts taken from the *American Chemical Abstracts* (1917 to Sept. 10, 1943, inclusive) and other material found in the library of the National Research Council of Canada. An index increases the usefulness of this publication and Miss Whalley is to be congratulated on her work. The abstracts deal with the chemical and biological properties of sixteen substances in all. Eight of these are obtained from bacteria, eight from fungi. Among the latter are penicillin, penatin and fumigacin, some of the properties of which have been noted in these columns recently. The properties of patulin were made known too late to be included in Miss Whalley's very useful compilation. As we go to press we learn from the *British Medical Journal* (Dec. 18, 1943, p. 800) that the January number of the *British Medical Bulletin* will be devoted to authoritative articles on, and a bibliography of, penicillin.

Rediscovery of Comet Daniel (1909 IV)

This comet was seen by Mr. G. F. Kellaway, West Coker, on Nov. 30d. 22h., and a few nights later his photographic results confirmed the position which he had adopted for it. Its magnitude at the time of discovery was 13, and it was very close to the place predicted by Mr. W. P. Henderson and Dr. H. Whichello, in the "Handbook of the British Astronomical Association", 1943.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Flow States in Emergent Gas Streams

As part of a study of factors affecting flame stability, some time ago we began an investigation into the influence of gas velocity on the flow conditions at a burner head; in the first instance unignited media were employed. The technique of instantaneous shadow photography was chosen as best for the purpose, and a preliminary series of experiments showed propane or butane as most suitable gaseous media; for, not only do the refractive indexes of these hydrocarbons differ widely from that of air, but, in addition, their immobility enhances the sharpness of the gaseous boundaries and the consequent clarity of the photographic records.

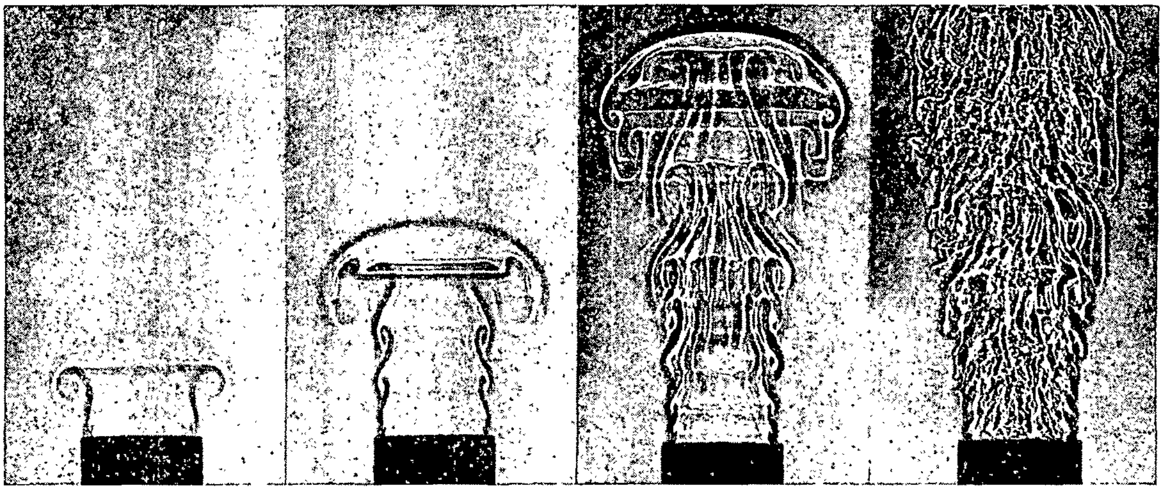
The accompanying photographs were obtained at intervals of 1/50 sec. after releasing propane abruptly from its confinement through a ⅜ in. diameter tube some 40 in. in length, the velocity of the stream increasing from zero to that adequate for turbulence.

Figs. 1 and 2 indicate the primary vortex, known as 'Overbeck's vortex', conditioned by the initial expansion of propane into the surrounding atmosphere; this is followed at successive intervals by secondary vortices. Previous records of such flow, though less clearly defined, have been obtained by F. C. Johansen[1] using liquids, by G. Burniston Brown[2] using illuminated smoke streams emerging from narrow rectangular orifices, and also at the National Physical Laboratory[3], where air intermittently heated by sparks was used.

Fig. 3 indicates a transition flow state before the attainment of velocities adequate to induce turbulence (Fig. 4). Under such conditions the rising column appears to become segmented and is possibly rotating.

Our present experience indicates that while the primary vortex is a common phenomenon at all speeds below the minimum for turbulent flow, secondary vortices develop more slowly the slower the gas velocity, the distance above the orifice for a given degree of development appearing to vary somewhat inversely with velocity; also, the higher the velocity the more closely does the first secondary vortex approach the sphere of action of the primary vortex. The development of the primary vortex is also accompanied by narrowing of the main stream, due to a transfer of gas. Under the conditions described, there are doubtless velocity and pressure gradients at the front of the stream; with the attainment of steady flow, the secondary vortices are less mature on emergence but develop abruptly, at distances above the port decreasing with increasing gas velocity.

The secondary vortices are of particular interest to us as, when developed, it would appear that they are the most likely source of the periodic expansions and contractions of the outer cone of a bunsen flame revealed either by Schlieren photography[4] or stroboscopically[5]. Also, when a non-aerated flame at an adequate feed velocity leaves a burner port but remains stationary some distance above, it appears to be sealed at the locus of rapid development of the secondary vortices.



1 2 3 4

Brown attributed the secondary vortices to the sensitivity of the stream to sound motions arising autogenously; indeed, he demonstrated their inducement by suitable sound waves from an extraneous source.

We are giving further consideration to some of the issues raised.

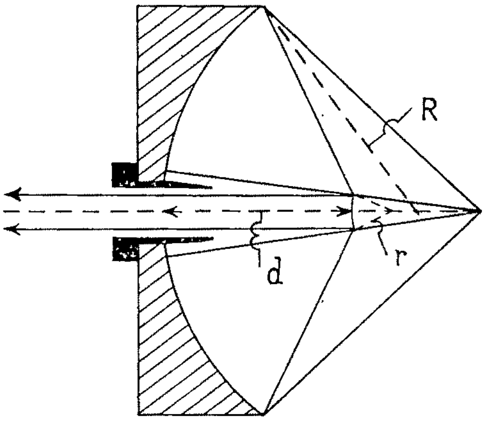
Reflecting Microscopes

I have read with particular interest the letter of E. M. Brumberg *et al.*[1] mentioning the use of a reflecting microscope involving two spherical mirrors since I have myself made three reflecting objectives; one of these was shown in process of figuring (N.A. 0·58) and one completed (N.A. 0·65) at the Physical Society's Exhibition in 1939. I used non-spherical



mirror-pairs, Schwarzschild aplanats[2,3], for a reason which may prove important if it is desired to exploit fully the possibilities of reflexion microscopy—I wished to reduce the fraction of the numerical aperture obstructed by the convex mirror.

Some astronomers say that though obstructing the central third of the numerical aperture of a telescope objective does not much hinder the resolution of a double star, and may even help it if the components are about equally bright, the effect on the resolution of a very unequal double is deleterious, and the effect on the visibility of low-contrast planetary detail markedly so[4]. They suggest that the 'obstruction ratio' should not be allowed to rise above 0·2, and should preferably be lower.

The bispherical monocentric approximation to the Schwarzschild aplanatic pair has an obstruction ratio of about 0·447. To reduce this while at the same time preserving exact anastigmatism, we must choose a pair in which both mirrors are non-spherical. If we are prepared to tolerate a moderate astigmatic coefficient, we need only figure one of the mirrors, provided the numerical aperture does not exceed about 0·65. To make such an aplanat (see figure) choose the ratio of radii of curvature of the mirrors to give the desired obstruction ratio: adjust the distance between them to the tabular value for freedom from coma, and figure the concave mirror to remove spherical aberration, continually readjusting the distance between the mirrors during figuring to preserve freedom from coma: this adjustment is very critical, and must be determined empirically. Fortunately it may be used to compensate for the spherical aberration produced by a cover-glass, without introducing serious coma. The table below assumes infinite tube-length, but will form an approximate guide when the tube-length is finite.

Intrinsic obstruction ratio	0·447	0·286	0·219	0·131
Radius of concave mirror, *R*	3·236	6·22	8·92	16·8
Radius of convex mirror, *r*	1·236	1·28	1·31	1·33
Approximate distance between mirrors, *d*	2·00	4·45	6·72	13·3
Approx. astigmatic interfocal distance in object space, at off-axis height *H*	0·00	$0\cdot142\,H^2$	$0\cdot209\,H^2$	$0\cdot270\,H^2$
Focal length	1·00	1·00	1·00	1·00

Only actual experience with different kinds of microscopic object and different methods of illumination can decide whether there is a benefit due to reduced obstruction which is worth the labour of aspherizing one or both surfaces. It may be that these two-mirror types will be abandoned in favour of D. D. Maksutov's ingenious 'solid' reflecting objective, in which the same air-glass surface, after acting as 'first mirror' by total internal reflexion, lets out the image formed by the second (silvered) surface, at normal incidence[5]. It may be found better to use the Schmidt principle: E. H. Linfoot exhibited in 1939 two Schmidt microscopes, N.A. 0·45 and 0·54[6,7]. He has since shown that a 'through-type' Schmidt microscope using two spherical mirrors exists: the Schmidt plate lies in the object-space, and can conveniently be made by aspherizing a normal-incidence 'immersion hemisphere'[8].

I have given the general condition for anastigmatism of two-mirror systems of finite tube-length in a paper in process of publication. I hope to give a fuller account of my three instruments shortly. For the present, I have had to lay this work aside; but not before I could satisfy myself with a few test slides and an eyepiece that at any rate the visual performance of these up-to-date versions of the ancient 'compound reflecting engiscopes' is substantially the same as that of their refracting counterparts.

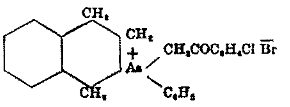
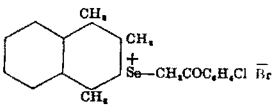
An Optically Active Selenonium Salt

WE have shown that *o*-β-bromo-ethyl benzyl bromide condenses with phenyl-dichloro-arsine in the presence of sodium to give 2-phenyl-1 : 2 : 3 : 4-tetrahydro-*iso*-arsinoline[1], which readily combines with *p*-chlorophenacyl bromide to give 2-phenyl-2-*p*-chlorophenacyl - 1 : 2 : 3 : 4 - tetrahydro - *iso* - arsinolinium bromide (I). This salt contains an asymmetric arsenic atom, and we were able to resolve it into optically active forms, the corresponding *dextro* and *lævo* *iso*-arsinolinium picrates having $[M]_D + 457°$ and $- 450°$ respectively in chloroform solution.



I



II

This use of the bromo-ethyl benzyl bromide for the synthesis of heterocyclic systems can clearly be widely extended. We find that the bromide condenses readily with sodium selenide to give seleno-*iso*-chromane, and with sodium telluride to give telluro-*iso*-chromane. The therapeutic properties of these novel heterocyclic selenium and tellurium compounds, and of their chief derivatives, are now being investigated.

Meanwhile we have combined the selenide with *p*-chlorophenacyl bromide to give 2-*p*-chlorophenacyl-seleno-*iso*-chromanium bromide (II). This compound contains an asymmetric selenium atom. We have therefore converted it into the *d*-bromocamphorsulphonate, which on recrystallization from alcohol ultimately acquired a constant rotation, $[M]_D$ −271° in alcohol. This salt in turn was converted into the 2-*p*-chlorophenacyl-seleno-*iso*-chromanium picrate, which had $[M]_D$ −496° in acetone solution, and into the corresponding mercuric tri-iodide, which had $[M]_{5893}$ −535°, also in acetone solution.

The acetone solution of the picrate retained its activity unchanged when allowed to stand at 16° for 20 hours, but underwent almost complete racemization when boiled for 1¼ hr. The solution of the mercuric tri-iodide underwent very slow racemization even at room temperature.

It is noteworthy that a dissymmetric arsonium halide such as (I) can racemize only by partial dissociation to a tertiary arsine and alkyl halide, that is, by the establishment of a 'dissociation-equilibrium' of the type $[abcd\text{As}]\text{Br} \rightleftarrows abc\text{As} + d\text{Br}$. A dissymmetric selenonium halide such as (II) can, however, racemize either by the establishment of a similar equilibrium, $[abc\text{Se}]\text{Br} \rightleftarrows ab\text{Se} + c\text{Br}$, or by direct racemization of the selenonium ion, that is, in compound (II), by direct oscillation of the *p*-chlorophenacyl radical above and below the plane of the ring. It is not unexpected, therefore, that the above selenonium picrate and mercuric tri-iodide are comparatively readily racemized.

The compound (II) is the second selenonium compound to be resolved into optically active forms: the first compound, methyl-phenyl-selenetine bromide, was resolved by Pope and Neville[2], who obtained the corresponding *dextro* and *lævo* chloroplatinates having $[M]_D$ +55° and −54° respectively.

We hope to resolve the sulphur and tellurium analogues of the compound (II), so that the rotatory dispersion of the three compounds can be compared.

An Antibacterial Substance from *Aspergillus clavatus* and *Penicillium claviforme* and its Probable Identity with Patulin

B. P. WIESNER, in a communication in NATURE[1] in which he acknowledges the help and advice of Prof. H. Raistrick, Mr. George Smith and Dr. Harry Coke, reported the preparation from *Aspergillus clavatus* metabolism solutions of a concentrate possessing relatively high antibacterial activity. Similar active non-crystalline concentrates were obtained from the same fungus by S. A. Waksman *et al.*[2] and investigated recently by H. W. Anderson[3].

We have isolated the active constituent from the metabolism solution of a strain supplied to us by B. P. Wiesner as a crystalline entity, from which a number of well-characterized derivatives could be obtained. Whereas Waksman called his crude active principle 'clavacin', we had adopted the name 'clavatin'. In its pure form it has m.p. 109·5–110·5° C. and forms a mono-acetyl derivative of mp. 118–120° C. Analysis and molecular weight determinations indicate an empirical formula $C_7H_6O_4$ for clavatin.

E. Chain, H. W. Florey, and M. A. Jennings[4] reported last year the isolation of a crystalline antibacterial substance from *Penicillium claviforme*, of m.p. 110° C., for which they suggest the name 'claviformin'. We have prepared claviformin according to the above authors and established its identity with clavatin by the usual chemical methods.

In a publication by Raistrick *et al.*[5] the isolation and chemistry of patulin from *Penicillium patulum* Bainier is described. In view of the close similarity of physical, chemical and biological properties of patulin and clavatin and of their derivatives, tabulated below, it is highly probable that these two substances are identical.

	Clavatin	Patulin
Empirical formula	$C_7H_6O_4$	$C_7H_6O_4$
Melting point	109·5–110·5° C.	111° C.
Melting point of acetate	118–120° C.	118° C.
Melting point of 2:4-dinitrophenyl-hydrazone	Darkens without melting	Darkens without melting
Melting point of phenyl-hydrazone	149–150° C.	152–153° C.
Melting point of oxime	152–155° C.	—
Melting point of methyl ether	69–70° C.	—
Antibacterial activity against *Staph. aureus*	1 : 64,000–128,000	1 : 64,000–128,000

The identity is further supported by our evidence from analytical experiments, collected during the past year, many of the results duplicating the findings of Raistrick *et al.* We have also isolated a reductive degradation product of clavatin identified as β-propyl-γ-butyrolactone. We have, however, obtained other experimental evidence, details of which we will publish elsewhere, which cannot yet be reconciled with the suggested structure for patulin.

Chemotherapeutic investigations have been carried out during the past year in association with Dr. F. C. Happold, Biochemical Laboratories, School of Medicine, University, Leeds. It is hoped that these results will be published in the near future.

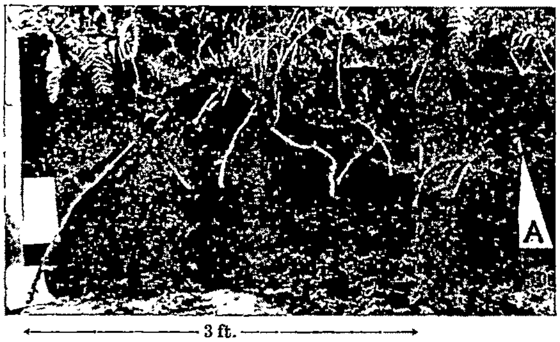
Rate of Growth of Bracken

FOR some considerable time, the widely held belief in the slow development of bracken plants and the initiation of the frond many months in advance of its expansion has been suspect. The idea of the old German morphologists[1,2,3] of the unfolding of one frond and the growth of one internode of the frond-bearing rhizomes in a season does not fit in with the rapid rate of expansion of the plants seen in the field.

In order to test the rate of growth of individual plants, two young sporelings (each 2–3 in. across and bearing some five to six immature fronds) were put into a trough formed by slabs of concrete 3 ft. wide and 2 ft. deep, so arranged as to form a long, narrow, continuous trough some 4 in. across. This was filled with rich soil, so that the sporelings were put under optimum growth conditions. The sporelings were planted out on March 29, 1943, and left until October 11, 1943.



GROWTH OF A BRACKEN SPORELING, PLANTED MARCH 29, PHOTOGRAPHED OCTOBER 10.
The underlying soil has been partially removed to show the numerous branches of the rhizome. *A*, an immature frond, some 8 in. below soil-level.

During that time—as the accompanying photograph shows—growth was very considerable: between August and October, the number and size of the fronds increased very noticeably until they extended over the whole of the 6-ft. trough.

When the concrete slabs at the front were removed, it was found that the rhizomes were ramifying through the whole of the narrow band of soil: so much so, that the rhizome of one plant had already forced its way out between the cracks of the slabs at the base of the trough and was turning towards the damp soil in the hedge-bank alongside; while in the other case, the rhizome had extended to the extremities of the trough and two branches had forced their way through into a partition behind.

One plant was removed from the trough: this was not easy as the rhizomes were overlapping very considerably with the adjacent ones; and at three places, in order to preserve the second plant *in situ*, the rhizome had to be cut. This extracted plant showed a mass of fronds and four main rhizome leaders.

Some of the points that may be noted are:

(*a*) The plant was carrying twenty-two green fronds and a number of withered sporeling ones; also a large number of immature fronds that had not expanded. All the green fronds were of the juvenile rather than the full adult form, and none of them bore spores. On each branch of the rhizome, the largest fronds were those nearest to the distal end of the branch.

(*b*) The lengths of the longest two branches of the rhizome (measured from the central region) were: 55½ in. (141 cm.); 30 in. (76 cm.), so that these gave an overall stretch of exploratory rhizome, after one season's growth, of 85½ in. (217 cm.). These branches were running outwards and downwards from the centre, and appeared to be limited in their downward thrust only by the concrete base of the trough. (There was about 20 in. of soil in the trough.)

(*c*) The number of branch shoots, each with its rhizome branch and frond bud already laid down, was considerable. In many cases, these fronds were so deep (8–10 in.) below the surface that they could not—at the end of the season—force their way up, and had rotted. Under adverse conditions in a hard winter, others may perish similarly; but after a mild winter, since a well-formed rhizome carries large stores of food, fronds already laid down would have an advantageous start in the spring.

(*d*) The initial fronds of the young sporophyte are so small that, unless abundant in the field, they would be overlooked. Moreover, this stage would be seasonal—possibly April–June—for under congenial conditions by July they would have formed plants 1–2 ft. across, which might double themselves by October. Such clumps have been reported in heather, but until now the fact that they could be one year's growth was not recognized. Here, apparently, is one of the explanations of the rapid spread of bracken.

Stimulation of the Milk Production of Dairy Cows by Feeding Thyroid-active Iodinated Proteins

GRAHAM[1], working at the University of Toronto, and afterwards at this Institute[2], demonstrated a marked temporary galactopoietic effect of both orally administered dried thyroid gland and subcutaneously injected thyroxine in dairy cows. This has been confirmed both in Great Britain[3] and in the United States[4]. In 1914 Morse[5] found that the effects of iodinated proteins on the metamorphosis of tadpoles were comparable to those of thyroid, and more recently (1939) Ludwig and von Mutzenbecher have shown[6], and Harington and Pitt Rivers[7] have confirmed, that thyroxine can be isolated from hydrolysates of casein treated with iodine (iodinated casein). The possible use of iodinated casein for the stimulation of milk production in the dairy cow was visualized by Bottomley and Folley[8], who carried out small-scale experiments with cows[9] which indicated that transient increases in milk production could be obtained by feeding iodinated casein.

In view of these results, a detailed investigation of the effect of iodinated protein on the milk production and clinical physiology of the dairy cow was commenced in the summer of 1941 under the auspices of the Agricultural Research Council, and experiments have since been carried out involving 208 dairy cows. Iodinated casein, iodinated whole blood, and iodinated 'Ardein' have been fed to dairy cows, and all three have elicited increases in milk production.

In the early stages of the work, unpalatability of the iodinated proteins and iodine poisoning of the cow were severe limiting factors, and it proved impossible with proteins of low thyroidal activity to obtain a response without the onset of iodism, the symptoms appearing when more than 2·7–3·0 gm. of iodine were fed per day. More active preparations, however, have given more promising results.

'Ardein', a commercial preparation of the ground nut (*Arachis hypogœa*) rich in the globulin, arachin, has been iodinated under semi-commercial conditions, and the iodinated 'Ardein', containing 0·88 per cent acid-insoluble ('thyroxine') iodine has been used in two experiments. When 50 gm. of this material was fed, milk production increased 35 per cent, and fat production 54 per cent. This was accompanied by an increase of 30 per cent in the resting pulse or heart-rate, 34 per cent in the resting respiration-rate, and a slight increase in the rectal temperature. In one of these experiments, no extra food was given to the cows to compensate for the increased metabolism, and, after seven weeks feeding with 50 gm. a day, the cows had lost 115 lb. of body weight or 9 per cent of their original weight. The shape of the weight-loss curve and the condition of the cows suggested that, in the latter stages of treatment, tissue protein was being mobilized to meet the increased energy requirement. Even after seven weeks treatment at such a high level, the clinical abnormalities shown by the cows were not so severe as was expected, and when treatment was stopped live-weight was rapidly regained. The subsequent history, performance, and postmortem appearance of animals subjected to such drastic treatment does not indicate that their health has been impaired.

Iodinated casein has been used in four experiments. It has been found that the response in milk production to a standard dose (30 gm.) of a highly thyroid-active preparation is dependent on the initial level of production of the cow. The response in pounds per day is greater the higher the initial yield ($r = +0{\cdot}7874$), but the percentage response declines with increasing initial yield ($r = -0{\cdot}4668$). As the main factor causing initial yield variation in these experiments was the stage of lactation of the cow, it is thought that response varies with the stage of lactation. This has been confirmed by experiments on the same cow at different lactation stages. The effect of lactation stage is interpreted as indicating a lower state of functional activity per unit of active mammary tissue during late lactation, and a larger amount of active mammary tissue in a higher state of functional activity in early lactation in the normal cow. It has not, however, proved possible to prolong, by iodinated casein feeding, milk production in cows approaching the end of their normal lactation period. Heifers and cows have responded equally well, no response differences have been found between cows at pasture and cows kept on winter rations, and Guernsey and Shorthorn cows have responded in a very similar manner.

It has been found that a dose of 15 gm. daily of iodinated casein increases milk production by approximately 16 per cent and 30 gm. daily by 33 per cent, indicating that the percentage response in milk production is directly proportionate to dosage within this range. The heart-rate increase and the percentage heart-rate increase, however, are nearly trebled by doubling the dosage, this probably indicating that at low dose-levels the increased metabolism is not reflected in an increase in the heart-rate. The relationship between the milk-yield response and the heart-rate response to iodinated proteins of different potencies confirms that at low milk-yield responses the heart-rate responses are proportionally lower than when the milk-yield response is high.

The galactopoietic potencies of iodinated proteins have been expressed in terms of the percentage increase in milk production per gram of iodinated protein fed. Potencies of 0·075 per cent for iodinated blood, 0·543 per cent for iodinated 'Ardein', and up to 1·096 per cent for iodinated casein have been found. There is a distinct, but not exact, relationship between the acid-insoluble ('thyroxine') iodine analysis of iodinated proteins and their galactopoietic potencies, but much better agreement with lactation response is shown by biological assays carried out with Xenopus tadpoles by Dr. A. S. Parkes.

Since the work was commenced, Reineke and Turner[10] have published the results of three-day feeding trials with dairy cows, using their own iodinated casein preparations. The results of these short-term trials also indicate that the milk production of cows can be stimulated by feeding iodinated casein.

The results reported above, together with much additional data on milk composition and the clinical effects of dosage, will be published later. Experiments are now in progress to find whether practical application of the results is possible, especially with regard to winter milk production.

My thanks are due to the Agricultural Research Council for grants in aid of this work.

A Scientific Directory

In recent months much has been said about the organization of science and, without prejudice to, or support for, any particular formula, there is one direction in which effect can be given in some measure to that aim, namely, in the provision for the British Commonwealth of a directory of scientists along the lines of "American Men of Science"[1]. Such a directory should be available in public libraries and research institutions and should serve to group together, in a manner hitherto entirely overlooked, those members of the community who conduct original investigations in the natural and exact sciences in any of the recognized branches. The concise style of entry, apart from the contentious practice of 'starring', adopted in "American Men of Science" is admirable for conveying the information that scientists have a right to expect to have regarding each other, and much would be gained in reducing the insularity felt by members of one branch *vis-à-vis* those of another.

The responsibility for the production of such a directory is beyond the purview of any of the scientific societies except perhaps the Royal Society, and it might not be too much to hope that the experience gained with the Central (Scientific) Register of the Ministry of Labour during the past few years could be made available for the project envisaged once stable conditions return at the end of the War.

RESEARCH ITEMS

Obstructions to the Ascent of Salmon

INFORMATION as to obstructions in Newfoundland and Labrador rivers is summarized in a paper by A. A. Blair, Fisheries Research Laboratory, Newfoundland (Salmon Investigations. 1: Obstructions in Newfoundland and Labrador Rivers. Research Bulletin No. 12 (Fisheries). Department of Natural Resources, St. Johns. Newfoundland Government, 1943). In Labrador the type of obstruction is, in all cases, falls; in Newfoundland, mainly falls, but sometimes shoals and dams. It is suggested that improvements could be made in 9 out of 18 rivers in Labrador, and in 36 out of 81 rivers in Newfoundland. Ready accessibility to spawning grounds is a highly important factor in the maintenance of any stock of salmon, and these obstructions made ascent of salmon difficult or impossible. This collection of data is a valuable one, and will help much in the planning of improvements. Information about Labrador rivers was obtained directly from fur trappers, and about Newfoundland rivers from river wardens. Some of the more accessible obstructions were inspected personally, and of these information is given in greater detail.

A Protozoan Parasite of Freshwater Fish

A. DUNBAVIN BUTCHER has investigated the life-cycle of a ciliate parasite of the rainbow trout, brown trout and carp ("Observations on Some Phases of the Life Cycle of *Ichthyophthirius multifiliis* Fouquet, 1876, a Ciliate Protozoan Parasite of Fresh-Water Fish". *Australian Zoologist*, **10**, Part 2; 1943. Royal Zoological Society of New South Wales). There was a severe outbreak of this so-called 'white spot disease' at the trout hatcheries of the Ballarat Fish Acclimatisation Society in 1939 and 1940. Following this, the author has succeeded in elucidating the complete life-history of the parasite, in spite of the great difficulties incurred in bringing about natural infection of the fishes in aquaria. The total time for the completion of the life-cycle was found to be 13–16 days, which probably accounts for the periodicity of the epidemics. The parasite feeds on the whole cells of its host. The most likely hypothesis for the cause of the death of the fish is probably that the parasite is the source of a toxin which is fatal.

Heterostylism

Linum grandiflorum exhibits the phenomenon found by Darwin that pin-flowered plants are not usually fertilized by pin-flowers, nor thrum by thrum. D. Lewis (*Ann. Bot.*, N.S. **7**, 115; 1943) has discovered that differences in the osmotic pressure of styles and pollen of thrum- and pin-plants will account for the phenomenon associated with heterostyly. The stigma of Linum is placed on one side of the style and is permeable to water, whereas the epidermis of the style is relatively impermeable. On placing in water, the style curls with the stigmatic surface on the convex side. In 30–40 per cent cane sugar there is curling in the opposite direction. The author shows that the pin-style is isotonic with 18 per cent sucrose and the thrum-style with 12 per cent sucrose. Pin-pollen is isotonic with 3 per cent potassium nitrate and thrum-pollen with 5 per cent potassium nitrate. Thus pin-styles have high and pin-pollen low osmotic pressures relative to thrum-styles and pollen respectively. The discovery of Darwin that pin-styles pollinated with thrum-pollen become twisted is shown to result from the abstraction of water by the germinated thrum-pollen from pin-styles. The ratio of osmotic pressures in both legitimate pollinations is 4 : 1, but is 5 : 1 and 7 : 1 in the two illegitimate pollinations. This disparity partly explains the differences in behaviour in illegitimate pollinations—non-germination of pin-pollen and the bursting of thrum-pollen tubes. The author suggests that non-germination of pin-pollen cannot be accounted for, however, by simple osmotic relations, but that imbibition in the early stages of pollen germination is controlled by cell colloids.

Phylogeny and Basic Number in Crepis

THE genus Crepis provides valuable material for the analysis of speciation in relation to chromosome number and morphology. One of the most difficult questions was related to the presence of species with chromosome numbers less than the basic numbers of the genus, which are generally agreed to be 6 and 5 in Crepis. H. A. Tobgy (*J. Genetics*, **45**, 67–111: 1943) has made a thorough and valuable study of the relationships of *C. neglecta* ($n = 4$) and *C. fuliginosa* ($n = 3$). These two species are closely related and will hybridize and give some fertile hybrids. The taxonomic position indicates that *C. fuliginosa* is a derivative of *C. neglecta* or a very similar extinct form. Morphology of the chromosomes in these species, like many other Crepis species, enables each component arm to be identified and followed in the hybrids. Tobgy shows that the *A* and *D* chromosomes of both species form one complex, while the remaining three chromosomes, *B*, *C* from *neglecta* and *B* from *fuliginosa*, form another complex. The interrelationships of the arms of the chromosomes are fully determined, but from the point of view of the reduction in number the behaviour of the *BBC* complex is significant. The *Bn* and *Cn* chromosomes have undergone a reciprocal translocation to give *B* chromosome of *fuliginosa* and a chromosome with the *Cn* centromere. The latter has been lost, since it was genetically inert. The mechanism is somewhat similar to that which originated Dubinin's six-chromosome *D. melanogaster*, and to that suggested by Darlington for such chromosome reduction.

A Direct-Intensity Microphotometer

EXPERIENCE obtained at the Observatory of the University of Michigan in the operation of the ingenious microphotometer installed there has been described by its designers (*Astrophys. J.*, **98**, 43; 1943). The instrument has two plate carriers, on one of which is placed the photograph or spectrogram under examination, and on the other, which can be moved transversely, a calibration photograph, usually an optical wedge or wedge spectrum. This latter is kept in step with the other longitudinally while being moved transversely by automatic means in such a way that the densities of the two plates are always equal. This transverse motion is transferred by means of a cam and mirror to the final trace, which then reproduces directly the relative intensities in the photograph under examination. Line contours in absorption spectra can be reproduced to better than one per cent of the continuum for plate densities between 2·0 and 0·1, while the speed of operation is such that spectrophotometric comparison of two continuous spectra can be carried out at forty wave-lengths over a range of 2500 A. in an hour and a half. The versatility of the instrument allows it to be used with 'standard spot' calibrations, as a transmission microphotometer, and as an isophotometer for use on faint diffuse objects. Many of these applications are illustrated by photographs and the corresponding tracings.

The Coronal Line Spectrum

A NOTE by P. Swings (*Astrophys. J.*, 98, 116; 1943) gives an account of a paper by Edlén (*Z. Astrophys.*, 22, 30; 1942) in which the Swedish spectroscopist publishes fuller details of his recent discovery of the origin of the emission lines in the solar corona. New identifications have been added to those already given (NATURE, 150, 756; 1942): a line occasionally observed at 5536 A. is attributed to A X, and the line at 4359 A. is given, though not with certainty, as due to A XIV; while λ 7059 is identified as due to Fe XV and λ 5694 as perhaps due to Ca XV. The cosmic abundance of argon is not known, but neon is known to be of frequent occurrence, and the ground-term splitting in A X is accurately enough determined to make the identification of λ 5536 very probable. As regards the theory as a whole, the experimental evidence adduced by Edlén from his investigation of the extreme ultra-violet spectra of Fe X, Fe XI, Ca XII and Ca XIII, from his extrapolation of the ground-term splittings in iso-electronic sequences, and from his comparison of transition probabilities with observed intensities, is entirely convincing. There can remain no doubt that the problem of the origin of the coronal lines is now solved. Only four lines (λλ 3454, 4567, 3801 and 4311) remain unidentified, the last two being very faint; all the rest belong to forbidden transitions in the highly ionized atoms of iron, nickel, calcium and argon.

Magnetochemistry

IN the ninth Liversidge Lecture (*J. Chem. Soc.*, 328; 1943) S. Sugden discusses some recent applications of measurements of magnetic susceptibilities to the elucidation of structure. The modern quantum theory has greatly clarified the interpretation of magnetic data, but difficulties arise when quantitative comparisons are made between theory and experiment. In considering molecules the contribution of resonance to the susceptibility becomes significant, and for more complex molecules only semi-empirical methods are available. Prof. Sugden discussed several examples. The effect of temperature and the significance of orbital moments were dealt with, some cases in which the latter cannot be neglected being mentioned. The applications to co-ordination compounds were treated and some difficulties in the present state of the theory which are outstanding were pointed out. The lecture gives an interesting and balanced survey of the subject with which it deals.

Polymorphism of Arsenious Oxide

THE common crystalline form of arsenious oxide (As_4O_6) is octahedral, but a monoclinic form was discovered by Wöhler in 1832 and there is also a glassy amorphous form. The system was investigated by Rushton and Daniels in 1926 by measuring the vapour pressures of the two crystalline forms, estimating the melting points as 275° for the octahedral and 315° for the monoclinic. J. H. Schulman and W. C. Schumb (*J. Amer. Chem. Soc.*, 65, 878; 1943) have made a further investigation of the system, including solubility, heats of transformation and X-ray and crystallographic measurements. They conclude that the monoclinic form is thermodynamically stable with respect to the more common octahedral form at temperatures as low as 2°, the transition temperature being approximately − 13°. Water vapour is effective in accelerating the transformation of octahedral to monoclinic As_4O_6 at 180°, whereas vapours of many other substances were found to be ineffective. The preparation of three new forms assumed by Smits and Beljaars (1931) was attempted without success.

Autoxidation of Ascorbic Acid

THE availability of ascorbic acid (vitamin C) is diminished through destruction by autoxidation. R. W. Peterson and J. H. Walton (*J. Amer. Chem. Soc.*, 65, 1212; 1943) have shown that in the absence of copper very slow autoxidation occurs below $pH = 8 \cdot 0$; it increases above this value, and in highly alkaline solution the rate is extremely high. In presence of copper the reaction occurs readily in both acid and alkaline solution. A marked autocatalysis was observed in the presence of copper. Hydrogen peroxide is among the products of the reaction. The inhibiting effects of many substances were determined. Except sodium citrate, all the appreciably effective substances contained one or more amino groups and one or more acid groups. In general, an increase in the number of acid groups or the number of amino groups increased the inhibiting effect. None of the compounds inhibited the reaction in the absence of copper.

Spectra of New Stars

AN important publication by Dean McLaughlin (*Pub. Obs. Univ. Mich.*, 8, No. 12; 1942) draws a generalized picture of the spectroscopic development of a typical nova, and suggests a physical interpretation of the observations which is new in some respects. A thorough survey of the course of seven bright novæ enables the author to compare the corresponding stages in their development in a way hitherto impossible to the reader of the many previous descriptive papers, owing to the absence of an agreed terminology. Five systems of absorption lines and seven of emission lines are distinguished, many of them existing concurrently. Fluctuations in the light curve are correlated with spectral changes and with velocity changes; and an attempt is made to reconcile the various temperature determinations. It is significant that the variations of temperature found are almost exactly the opposite of what would be expected were the outburst due to a simple heating and subsequent cooling of the surface of a star. The changes are interpreted as due to a continuous emission of stellar material from a thin superficial layer at a rate which varies much as the light emission does, reaching a maximum just before light-maximum and dropping sharply soon after. The velocity of the ejection is not necessarily related to this rate, and indeed reaches its maximum long afterwards. The older theory of the successive emission of discrete shells is abandoned in favour of one in better accord with present ideas of what constitutes the photosphere of a nova. The question of the source of the energy released below the surface of the star is left open.

THE SPANISH IRON AND STEEL INDUSTRY

N a recent issue of *Dyna* (Revista de la Asociacion Nacional de Ingenieros Industriales de España) a aper by Señor F. Millan on "Spanish Metallurgy ince the National Movement", read at Barcelona omewhat earlier, is given in full. It is confined ntirely to iron and steel and steel manufactures.

After the War of 1914–18, production of Spanish on and steel gradually increased until, in 1929, that pig iron was about 722,000 tons and of steel just er 1,000,000 tons. It declined, of course, rather stically during the revolution, but in recent years recovered somewhat, though not up to the 1929 el. In 1942 pig iron was about 500,000 and steel ,000 tons. The most serious difficulties in the way real progress are lack of good metallurgical coke d scrap, to which must now be added a lower rade of native ore.

Until recently Spain had been noted for the high uality of its iron ores, with up to 60–70 per cent etallic iron content; but the average percentage ppears now to be in the neighbourhood of 40 per ent, and it has larger contents of sulphur and hosphorus. In 1940 output of ore was nearly 000,000 tons, but domestic consumption was only st over 1,000,000 tons and exports almost negligible, that large stocks accumulated at the mines, many f which had to close down at least for a time, and roduction during the first half of 1941 was only 97,000 tons. Before the revolution more than 0 per cent of the output had been exported to England, Germany and Belgium, the red hæmatites eing particularly in demand. The chief mines are n Vizcaya, Santander, Granada, Teruel, etc. An nteresting account of some of the magnetic iron ores f El Teuler and one or two other places has been iven by H. Quiring (*Z. prakt. Geologie*, **46** and **47**; 938–39). Geological estimates of the remaining eserves, after allowing for 325 million tons mined, re roughly 700 million tons. So far as Vizcaya, the chief mining centre, is concerned, the bulk of the remaining ores are carbonates with only about 30 per cent hæmatite. The carbonates are rather high in sulphur (up to 1·7 per cent) and the hæmatites in silica. The iron content of the latter, too, is only about 40 per cent. This all adds to the amount of coke required in smelting, of which there is already insufficient supply.

Although the manganese ore deposits are fairly considerable in places, such as those in Huelva and Teruel, output is very low. Thus in 1940 it was only 6,850 tons of ore, to be increased, it was hoped, to 10,000 tons in 1943. Metallic manganese content ranges from 37 per cent in Huelva to 53 per cent in Buferrera.

Spain has also considerable supplies of native coal, but not very much of it appears to be of the right kind for metallurgical coke production. At the Geological Congress at Toronto it was estimated that Spain's coal reserves were some 8,768 million tons, of which three fourths would be bituminous. Some of the principal coal centres are in Asturias, Teruel, Leon, and Palencia. The Spanish coal output in 1929 was 7½ million tons, and 2 million tons were imported together with nearly 300,000 tons of coke. Native coal production has increased somewhat in recent years, up to about 10 million tons in 1942, despite shortage of equipment, such as explosives and timber; and owing to the practical impossibility of importing good coke from Great Britain and Germany, native coal had to be used for the purpose, to the extent of 500,000–600,000 tons of coke. Much of this native-made coke, however, has a high ash content, up to 16 per cent or more, as compared with only 8 per cent in good English coke.

Yet another difficulty, to which reference has been already made, is the shortage of scrap for steelmaking. Attempts have been made to overcome these difficulties—lack of coke and of scrap—by means of the Krupp-Renn process, introduced into Germany about 1933–34, and fully described by Johannsen (*Tech. Mitt. Krupp Forschungsber.*, and also *Stahl u. Eisen*, 1934 and 1939). This method, in which huge rotary furnaces are used, something like cement kilns, is claimed to be particularly suitable for low-grade ores and can be used with almost any kind of fuel, including powdered coal or lignite. The ore is first reduced to a pasty condition, and then at a temperature below its melting point is converted into low-carbon compact lumps embedded in slag, from which the lumps are separated by a crushing process.

In his later paper (Sept. 1939), Johannsen included not only direct production of steel but also the application of the method to the reduction of non-ferrous ores. At that time it appeared there were about eighteen Renn furnaces in operation, but not more than half a dozen were in Germany; most of the others had been sent to Japan, where the process is more largely used than in Germany itself, probably due to the low grade of ore with which Japan has for the most part to be contented. According to latest reports, Japan is at present using eleven of these furnaces, of which four are in Manchukuo and seven in Japan and Korea. It is stated that six more were recently under construction in Manchukuo.

So far as Spain is concerned, progress in this matter has been rather slow. Apart from a concession granted to the Soc. Gen. de Electro Metalurgia to instal one of these plants in Aviles, Asturias, for an output of 30,000 tons of steel a year (to be doubled later) little else has been done, although the Instituto Nacional de Industria has sent a special mission to Germany to study the Renn process. According to Señor Millan, a trial plant may be put up in Vizcaya.

Señor Millan seems to be of the opinion that, if it is seriously intended to make Spain self-supporting in regard to iron and steel production, the best hopes lie in the direction of the so-called sintering (*sinterizacion*) methods, now so largely used in Germany with low-grade ores—to the extent of 35 million tons of ore in 1943; and he deals with these possibilities at some length, including the proposed adoption of the Sturzelberg and Norwegian Tysland hole methods.

Señor Millan includes a review of some of the principal Spanish producers of iron and steel, of which the chief is the well-known Soc. Altos Hornos de Vizcaya, with a capital of 250 million pesetas, and a maximum total capacity of nearly 700,000 tons p iron a year. It has its own coal mines, coking pla , by-product recovery plant, rolling mills, etc. Several other fairly large companies are noted, and an interesting point about many of them is the increasing attention being given to manufactured steel, for which purpose many new rolling mills and other technical equipment have been installed in recent years.

SOVIET WAR-TIME SURGERY

WHEN four British surgeons flew to the U.S.S.R. and stayed there for three weeks, they were given a great welcome and were taken not only to medical institutions in Moscow but also up the line so far forward as Vyazma to study the field and mobile hospitals. They learned that the Soviet surgeons have no new fundamental principles to teach us and do not need to learn any from us; their principles are the same as ours and differ only in the details of their application[1]. But young Russian surgeons would benefit from a study of our best hospital practice and our young surgeons would learn much from the Russian clinics. The methods of some Russian surgeons are notable. Prof. Yudin, for example, apart from his remarkable operation for replacement of the obstructed œsophagus by the jejunum, differs somewhat in his use of the skin-tight plaster for the treatment of war wounds. This method has been attributed to the Soviet surgeon Pirogoff, who, when he was short of splints in the Crimean War, cut out sailcloth to the patterns required and dipped these in plaster. This closed-plaster method was developed by Trueta in the Spanish Civil War. The closed-plaster method has been also attributed to Trueta himself, to Winnett-Orr in the United States, to Mettita in Italy and to Ollier in France.

While neither Soviet nor European anæsthetic practice is so good as it is in Great Britain or the United States, the Soviet system of blood transfusion was found by our visiting surgeons to be beyond criticism and it is done on a huge scale[3]. In one Moscow institution alone 500–800 donors are bled every day and 90 per cent of them are women. Donors get extra rations and also pay, but four-fifths of the money is returned for war purposes. There is never any lack of blood; it is flown to the front and has even been flown to Soviet wounded behind the German lines.

Another valuable feature of the Soviet Army Medical Service is the practice of sorting out all types of case in clearing stations five miles behind the firing line. This is done by an experienced surgeon and the cases are then sent to specialist hospitals, where they are treated by specialists in the kind of injury from which they are suffering. But before they are sent away they receive immediate treatment from young members of surgical teams, who are trained to give the treatment which the senior specialists expect them to have had. The clearing stations immediately behind the front are well equipped and each has a series of special units complete in itself. Perhaps this system—and the tough Russian constitution—has helped the Russians to return 70 per cent of their wounded to the firing line. Some of its features were shown in a film given to the Royal College of Surgeons last October[4]. This film was made two years ago. It showed the rescue of wounded by sledge, the method of giving each patient a bath, a shave and a general clean-up, and some of the methods of rehabilitation of function after injuries. It also showed some of the wards, which are less formal than those in British military and other hospitals.

The Russian military nurse awoke the admiration of the visiting surgeons. She not only does her job very well but also helps to build the hospital in which she works, cutting down trees, squaring up timber, making the frames of windows and doors and digging foundations. The British surgeons were impre her skill in camouflage. On one occasion they in what appeared to be a forest; it turned be the entrance to a hospital containing a th beds. Some of the buildings had been built the trees, which projected through the roofs is reminded of a certain medical unit at M Basra, during the War of 1914–18, at which t huts were built round the palm trees in this the palm trunks made useful wardrobes.

The medical service of the U.S.S.R. is becor woman's service, 90 per cent of the doctor under training being women. They take a fiv course, while a nurse's course has been reduce three years to two.

The British surgeons were also much impre the emergency medical service in Moscow, the ization of which recalls the organization National Fire Service in Britain. Moscow is di into areas, a map of which enables telephone oper detailed for night duty to send, within a few mi in response to a call for medical help, a well-equi ambulance, with a doctor, a nurse and an or to the house requiring them. The central op uses a device which illuminates on the map city the street from which the call comes and the nearest ambulance depot, with which she communicates. There would appear to be no r why cities in Britain should not be supplied with valuable service.

Soviet military ophthalmology has recently described by Prof. Kolen, head of the Novosil Eye Clinic[5]. Evidently it is obtaining good re in its treatment of the dangerous and distre injuries which involve not only the all-important but also the neighbouring organs and the fac general. Wound-healing by the transplant of tissues is also widely practised[6]. Dead ti treated with chloraclyde are used as an ai healing up fresh and granulating wounds, regeneration is stimulated with emulsions embryonal tissue obtained from guinea pigs used in castor oil as a liquid base.

UTILIZATION OF BAMBOOS I INDIA

AS is well known, in tropical and subtropi countries where the bamboo in one or m of its many genera and species flourishes, man, represented by the local population, has over v long periods of time made extensive use of it—in fa from house construction down to the provision of woman's household utensils and even part of clothing. The bamboo has probably been as serv able in an all-round fashion to man as any ot single vegetable product. It is of interest, therefor follow its more modern uses by civilized man has long discarded its former utilitarian ones.

In a Utilisation brochure issued by the Fo Research Institute, Dehra Dun (*Indian For. Rec.*, Res. Pub., Dehra Dun, 1943), V. D. Limaye descr some investigations into "Bamboo Nails, Manufacture and Holding Power". The investi commenced owing to the fact that wire nails had ome very difficult to obtain in India, while the de- ad for packing cases, not least for army require- ats, had increased enormously. Experiments were ried out to see how bamboo nails compared in hold- power and other qualities with wire nails. The ults of the tests are given; and sketches of large- production of bamboo nails are included and the ss of manufacture described.

uly India is a fortunate country when her care- supervised forest wealth enables her to confront ifficulty after another in times of dire stress h the work of her research officers. "It has und", says the author, "that glued bamboo ave a greater holding power than plain iron der a steady pull. But when shocks and rtation hazards are met with, their holding diminishes". A small percentage of iron nails acking case is, therefore, necessary, especially xing the battens by clinching. It was found ctual tests that if 25 per cent iron nails and er cent bamboo nails are used, a strong and eable box results, with a very considerable saving ts of manufacture.

ther use of the bamboo has been found in the facture of pill or ointment boxes. Due to a age of metal, various substitutes have had to be in the construction of containers; thus plywood iners have already been mentioned in NATURE *For. Leaf.* 24 and 26). In Leaflet 39 (1943) Sultan mmed discusses the method of making from boo small pill and ointment boxes. Details of ufacture are given including some information uitable coatings and linings. It is said that a y competent turner will find no difficulty in ing these boxes with the aid of a lathe and ordin- ools. The description is of interest: "A bamboo iner consists of a short length of bamboo (accord- o size of container required) which forms the of the body and lid of the container. The top the bottom are made of thin three plywood and rovided with a locking device so that, if the becomes loose due to climatic changes, the lid still be held tight. The container is usually coated inted, both inside and outside, with the object tarding the absorption of moisture by sealing pores of the bamboo, and to give a smooth clean sh."

THE SCIENCE OF TOMATO GROWING

HE Cheshunt Experimental and Research Station has devoted its energies during war-time wholly the elucidation of problems connected with food ps. Reports of investigations on the tomato upy most of the twenty-eighth annual report, for 2, of the Station (from the director, Dr. W. F. vley, The Nursery and Market Garden Industries' elopment Society, Ltd., Turner's Hill, Cheshunt, ts, 1943). Trials of the value of muriate of potash gainst sulphate of potash resulted in a small, gh scarcely significant, increase of crop in favour he sulphate. No harmful foliage effects were rved when muriate was added, and it would that widespread doubts about the suitability of ate of potash for the indoor tomato crop are dispelled.

h research has been devoted to diseases and pests of the tomato. Two varieties, Manx Marvel and Riverside, showed significant resistance to the wilt fungus *Verticillium albo-atrum*. Tomato stem-rot caused by the fungus *Didymella lycopersici* caused widespread damage in 1942 to plants growing in the greenhouse and in the open. The disease appears to be carried from crop to crop on wire supports and strings, and may be controlled by suitable methods of hygiene. Experiments have also been made with fungicides as soil treatment, or applied as sprays and dusts to the plant, or as a protection of the 'collar', where infection normally occurs in greenhouse tomatoes.

Control of the wireworm pest by trapping with carrot bait gave rather disappointing results, and the elimination of these larvæ still remains one of the outstanding problems of pest control. Other negative results were obtained with sprays containing tartar-emetic and glycerine, advocated in the United States against the red-spider mite, and with potassium iodide solution for the prevention of damage by the root-knot eelworm.

Tomatoes in sand culture exhibited clear-cut symptoms when deprived of boron, manganese and magnesium. Omission of boron and magnesium from the culture solution produced marked stunting, and boron deficiency caused a leaf scorch similar to that sometimes associated with acute potassium starvation. Lack of magnesium induced a withering of the tips of leaflets, whereas the absence of manganese brought about a mottling of the leaf with uniform yellow specks. The report contains details of these and other investigations in the form of short papers by the authors of each subject for research.

HYDROGEN EXCHANGE REACTIONS

IN two papers (*J. Chem. Soc.*, 361, 367; 1943) H. V. A. Briscoe and co-workers describe the results of experiments on the interchange of hydrogen isotopes with complex salts, ammines of cobalt, and platinum and palladium being studied. The hydrogen of $[Co(NH_3)_6]\,Cl_3$ and $[Co\ en_2]\,Cl_3$ (en = ethylenediamine) undergoes isotope exchange with heavy water (D_2O) in solutions, the interchange following a unimolecular law with a rate inversely proportional to the hydrogen ion concentration but practically independent of the ammine concentration or its deuterium content. The exchange mechanism is explained by assuming that the metal ammine group $M—NH_3$ can ionize as an acid: $M—NH_3 = M—NH_2' + H^{\cdot}$, this being parallel to the ionization of aquo-ammines, which form hydroxo-ammines. There is some evidence that the case of acid dissociation runs parallel with the stability of the ammines. The reaction mechanism is very fully discussed in the papers on the basis of the kinetics.

The rate of interchange of hydrogen isotopes with ammines of different metals decreases in the order Co > Pt > Pd and runs parallel to the complex ions. In the case of $[Pd(NH_3)_4]\,Cl_2$ the interchange mechanism is complex; in addition to the acid dissociation mechanism, it reacts in acid solution by reversible dissociation of ammonia from the complex. This points to a continuous gradation between the two extreme types of ammonia complexes represented by the stable metal ammines of the $[Co(NH_3)_6]\,Cl_3$

type and the unstable ammoniates of bivalent cobalt, nickel, copper, etc. The function of the nitrogen atom of the ammonia molecules as a centre of co-ordination has perhaps not been sufficiently emphasized in the past, and its tendency to assume a configuration similar to that of the ammonium ion in the stable compounds, which then dissociate as substituted ammonium salts, should apparently also be taken into account.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Tuesday, December 28

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Prof. E. N. da C. Andrade, F.R.S.: "Vibrations and Waves", 1: "Vibrations".*

Thursday, December 30

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Prof. E. N. da C. Andrade, F.R.S.: "Vibrations and Waves", 2: "Wave Properties in General".*

Friday, December 31

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. A. J. Philpot: "Paints and Protective Finishes for Metals".

Saturday, January 1

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Prof. E. N. da C. Andrade, F.R.S.: "Vibrations and Waves", 3: "Sound Waves".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Technician for the Veterinary Laboratory—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (December 28).

Master to be responsible for the teaching of Mathematics at the Bristol Junior Technical School—The Chief Education Officer, 2 Cecil Road, Clifton, Bristol 8 (December 29).

Assistant Lecturer in the Mining Department—The Principal, County Mining and Technical School, Nuneaton, Warwickshire (December 31).

Principal (temporary) of the Bridgend Mining and Technical Institute and Junior Technical Schools—The Director of Education, County Hall, Cardiff (January 3).

Assistant Master to teach Mathematics in the Day School—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex (January 3).

Master or Mistress (temporary) for Science, including Elementary Biology—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17 (January 3).

Assistant (part-time) in Speech Training in the Department of Education—The Registrar, The University, Manchester 13 (January 10).

Science Master, mainly for Chemistry, up to University Scholarship standard, at the City of London School—The Town Clerk, 55–61 Moorgate, London, E.C.2 (January 12).

Chair of Chemistry—The Principal, University College of Wales, Aberystwyth (January 15).

Regius Professor of Zoology at Glasgow University—The Private Secretary, Scottish Office, Fielden House, 10 Great College Street, London, S.W.1 (January 17).

Demonstrator in Anatomy (male)—The Secretary, Guy's Hospital Medical School, London Bridge, London, S.E.1.

Laboratory Steward for the Chemistry Department—The Principal, Coventry Technical College, Coventry.

Assistant Inspectors I and II (covering Groups A and B) for posts (London and Provinces) in a Government Department. For Group A posts sound technical and practical training in Mechanical Engineering is required, preferably in Heavy or Marine Engineering or in Modern Engineering Production Methods; for Group B posts sound technical and practical training and experience in Mechanical Engineering is required, with special knowledge of Foundry Practice, the Nut and Bolt Industry, the Metallurgy of Ferrous and Non-Ferrous Metals, or the Armour Plate Industry—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Advertising Section, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.1952A, and grade and group for which application is being made).

Works Engineer (Order No. 275) with good experience in Plant Maintenance (including Electrical) and Lay-outs of New Projects required; a Metal Shops Superintendent (Order No. 262), with Machine Shop experience essential and Coppersmith experience desirable; an Assistant Chief of Production Control (Order No. 274), must be thoroughly conversant with Engineering Procedure and Operation of Works Documents, with good administrative ability and experience in dealing with large staff—The Ministry of Labour and National Service, A.O., 16 Westwood Road, Southampton (quoting appropriate Order No.).

Plantation Assistants in the Cameroons under the Custodian of Enemy Property, Nigeria—The Ministry of Labour and Nation Service, Central (Technical and Scientific) Register, Advertising Section, Alexandra House, Kingsway, London, W.C.2 (quoting Referenc No. F.1888).

Lecturer (temporary) in the Department of Building and Structural Engineering—The Principal, Central Technical College, Suffolk Street, Birmingham 1.

Chief Planning Engineer at a well-known Airframe Manufacturing Concern in the London area—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Advertising Section, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.1951XA).

Graduate Assistant Master to teach General Science with Mathematics in Day Technical School and Evening Institute—The Principal, Technical Institute, 28 Beckenham Road, Beckenham, Kent.

Assistant Lecturer to teach Engineering Subjects, including Science, Mathematics and Drawing to day and evening students—The Principal, Forest of Dean Mining and Technical School, Cinderford, Gloucestershire.

Assistant Master or Mistress to teach Geography, and an Assistant Master for Engineering Subjects, at the Burton-upon-Trent Technical Institute and Junior Technical School—The Secretary and Director of Education, Education Offices, Guild Street, Burton-upon-Trent.
